In spite of this favourable record, it must be acknowledged, however, that the sanitary state of Tangier is most deplorable. Nevertheless, the Moors are, in one respect, more advanced than the French and the municipalities of many Spanish and Italian towns. They, at least, admit direct drainage into sewers, and believe in the practibility of small sewers. At Tangier there are two main sewers, both sufficiently large for a man to enter. The principal sewer passes through the ravine—that is, the lowest portion of the town—and empties itself under the small landing stage in the bay. It is about a yard wide and a yard and a half high; the roof is domed, and the invert but slightly concave. This sewer runs a distance of a thousand yards, and during heavy rains is often completely filled. It is said to have been originally built by the Romans, but was probably in part rebuilt during the English or the Portuguese occupation. The other main sewer crosses the town more to the east, at a somewhat higher level, and passes under the British Legation. From all the neighbouring small streets, innumerable small sewers converge to these two main drains. These little sewers are very badly constructed of rough masonry and tiles. They are often stopped up, and burst. They invariably leak, and contaminate the surrounding soil. They are not deep enough in the earth, and fall into the top [illegible] of the lower portion of the main sewer. Thus they convey back to the houses the gases accumulated in the main as well as in the branch drains. Nor have the Moors any idea of making traps, or of ventilating or systematically flushing the sewers. On the other hand, their ploughmen as [illegible]

street. Also all the water used in Tangier goes into the house drain, and is not, as in France, wasted by being thrown into the gutter. All the water used helps to flush both the house drain and the public sewer. The Moors, to their credit be it said, use a great deal of water. If they could only be induced to trap their closets, the drainage of Tangier might compare favourably with many continental towns, and would be preferable to Marseilles or Toulon. Some of the worst houses in Tangier are those built for Europeans, especially for the Spaniards. The closets of these have been carried further within the houses, and are not trapped. Other drains are opened in the [illegible] the kitchen; thus the sewer poisoning is more complete and more thoroughly distributed over the entire house.

Anyone, however, who settles in this country may to a great extent protect himself efficaciously against the surrounding bad sanitation. He will not be harassed by police regulations that are opposed to the laws of hygiene. In France, for instance, there is a police ordinance to the effect that soil pipes must measure nine inches in diameter, though experience has proved that the size should not exceed three or four inches if the pipe is to be self-cleansing. Then a cesspool or a *tinette* is imposed, and, as often as not, the cesspool is built immediately under the house, so that anything like effective interception is impossible. As a rule the whole of the drainage is sent to the sewer. There is an English plumber in the town, with all the necessary sanitary appliances, and for a small cost the house drains may be trapped and ventilated according to the most approved system. If the interior of the houses is in a bad condition, this is entirely the fault of the owners or occupiers. Half the difficulty can be overcome. Nor would it be impossible to obtain permission from the Sultan to substitute good earthenware pipes, properly laid, for the miserable little tile-built drains, which so often burst and poison the atmosphere of the by-streets. Unfortunately, the Diplomatic Corps are not a body of sanitary reformers, nor does it seem possible for them to act in unison with respect to any matter whatsoever. The Moorish authorities, on the other hand, will not move except under pressure, and united pressure, from without. Anything like precaution or forethought is opposed to Moorish customs and beliefs. It is quite useless expostulating on the danger of epidemics. If such a scourge arrives, it is the will of Allah, and it is neither right nor possible to attempt any resistance. But even if the sewers of Tangier cannot be rebuilt, the town is small, and it is easy to find villa accommodation beyond its walls. So far as the hotels are concerned, [illegible] proprietor of the Continental Hotel, for instance, has not only installed good English closets, but has caused the whole of the sewer passing along the street in front of his premises to be rebuilt. Thus, if the Moorish authorities will not act themselves, they do not oppose others taking the matter in hand. Villas outside the town must of course drain into cesspools, as the sewers do not go beyond the city walls. But land is still cheap, the villas are generally surrounded by good-sized gardens, so that the cesspools may be, and generally are, built at some distance from the dwelling. All the ordinary methods of trapping, ventilation, and interception can therefore be applied, and every precaution taken against the ingress of sewer gas. There are beautiful sites within a few hundred yards of the town where clusters of villas and hotels could be built on the best sanitary principles. No Government interference would prevent the creation of a small Hygiea, where perfect sanitation would unite with an almost perfect climate to constitute an ideal health-resort.

In the meanwhile, the town remains in a [illegible] and, to some extent, dangerous condition. While there is free access of sewer gas into the interior of the houses, the streets outside are in a filthy state for want of proper scavenging. The water-supply, at one time exceptionally good, is becoming more and more exposed to contamination. To the east of the town, the district known as the Ras-el-Ma (the head of water) is composed of a layer of sand some seven to ten yards deep. Beneath the sand [illegible] a very broad stratum of shistose clay. The rain [illegible] through the sand, is checked in its downward course by the clay, and then flows by gravitation to the [illegible] plateau, which is sixty-four metres [illegible] Romans built a great number of small [illegible] with tiles placed a little apart from each other, so that the water might run in between them [illegible] all [illegible] aqueduct which passes [illegible]

Digitized by Google

to the Marina after travelling a distance of 1400 metres. This large canal or collector must have been most admirably built to have resisted so many centuries of ill-usage. On reaching the town there are two derivatives from the main aqueduct; one goes to the Sultan's mills, the other to the Fuente Nueva; but both these are now stopped up, and there only remains in working order the principal canal, which, passing under the large *soko* (or market) down the main street, supplies the fountains of this street and the Mosque at the further end. In its course through the town, the water may be contaminated by the leaking sewers that pass under it, over it, and by its side. Also the land at Ras-el-Ma, formerly uninhabited, is now dotted over by villas and a cluster of huts occupied by natives. Not only do these people to some extent contaminate the soil, but the land which is not built upon is being brought under cultivation—that is to say, covered with manure. It is true that a sample of the water taken and analysed in 1882 still proved exceptionally pure, and was compared for its excellence with the water brought to Seville by the English company; still it is evident that, as the population increases on this spot, the quality of the water gathered from the soil will be impaired. Herr Meis Barger, an Austrian engineer resident at Tangier, with the authority of the Government, investigated the whole condition of the water-supply, and states that half the small drains which bring the water from the soil to the aqueduct are now broken and useless. These he proposes to lay bare and reconstruct, and calculates that the whole work of restoration would only cost £6000. Further, he would constitute a large reservoir containing 10,000 cubic metres of water to be delivered in the town through iron pipes. Thus, in dry seasons a reserve supply could be drawn upon, and the iron pipes would prevent contamination from the proximity of the street sewers. By these means the water-supply could be doubled, and give each inhabitant of Tangier twenty-five litres per day. Instead, however, of relying on the surface supply derived from the sand, it would be preferable, as there are no springs at hand, to dig artesian wells, and then there would be no longer any reason to apprehend that the growth of the town will endanger the purity of the water. At present many persons drink only rain-water obtained from the roofs of their houses. This is stored in large tanks under the houses, which are seldom cleaned with sufficient care, and which occasion a dampness injurious to health. Others, in their ignorance, avail themselves of the numerous wells in and about the town, though the water is often highly charged with organic matter. This is especially the case with respect to some wells at a lower level than the cemeteries to the west. Under these circumstances, it is necessary for all visitors to boil and filter their drinking-water, and to make it a duty to complain as lustily as possible, so that the long promised waterworks may at last be taken in hand; in fact, the European population, by united action, have it in their power to make Tangier one of the most enviable pleasure and health resorts within comparatively easy access.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE NEWCASTLE JUBILEE EXHIBITION.

On the 11th of this month our exhibition is to be opened by his Royal Highness the Duke of Cambridge, who is to be the guest of our eminent citizen, Sir W. G. Armstrong, at Cragside, Rothbury. The full title of the exhibition is the Newcastle-on-Tyne Royal Mining Engineering and Industrial Exhibition. I give it here, and hope it will not be necessary to repeat it often. The exhibition will include a very great number of objects of general interest, but it will also cover many subjects of medical or sanitary interest, and of these, so far as they are likely to prove welcome to your readers, it will be my duty to write about from time to time in this correspondence. I have (as your representative) received an invitation from the Executive Council to join the private inspection of the exhibition which is to take place on Saturday next, the 7th; but as it is requested that no notice of the exhibition is to appear in any paper until Monday next, the 9th, I must reserve my remarks until then. We are to have another great exhibition here during the coming summer—namely, the Royal Agricultural—at which his Royal Highness the Prince of Wales has promised to be present, so that our northern city is likely to attract a large number of visitors this coming summer.

AN OUTBREAK OF TYPHUS IN NEWCASTLE.

There has been an outbreak of typhus fever in the east end of Newcastle, confined to two or three of the poorer streets, and densely inhabited by not the best class of working people. Already about eighteen cases have been admitted to the Fever Hospital. It is the opinion of our medical officer of health, Mr. H. E. Armstrong, that the disease has been imported into our city by some strangers. I am happy to report that there has been no fresh case since the 25th of last month. While on the subject of fever, I may here allude to the facilities for its study which will be afforded to students at the new and very complete hospital just erected for the city at Heaton. Seeing that the study of fever is not at all attended to by students in England as in Ireland, it is now recommended to be taken up by candidates for the licence in Sanitary Science of the University of Durham and for the M.B.

THE HARDY NORTHMEN.

All this spring, so far, we have experienced a good deal of the dull grey weather which is said by the poet to make "strong Englishmen." This has been accompanied by cold east and north-easterly winds, very trying to all but the very strongest constitutions. Nothing daunted, however, "the bathing season," we are told, set in yesterday, when the Tynemouth Amateur Swimming Club had its first "outing," or first "inning" perhaps I should say, as it is stated that yesterday, after an appropriate speech by the mayor to an assembly of about sixty, "a rush" was made by most of those present into the sea, where they appeared to thoroughly enjoy themselves. Scarcely much behind us on the other side of the Tyne, the swimming folk of Shields took the water to-day, and before doing so they were addressed by the president, the worthy Alderman Nelson, J.P., who stated that he had bathed in the sea 105 times this year already. Comment on this is needless.

SUNDERLAND.

It is very pleasing to hear that the Sunderland Workmen's Exhibition during the month it was open made a profit of about £500. This will be handed over to the funds of the infirmary there, which is free and also well supported by Sunderland artisans.

The vacancy in the staff for an honorary physician at the Newcastle Dispensary is likely to be filled up by the appointment of Dr. Beatley, of this city, who is the selected candidate, and who previously held the office of resident medical officer with much satisfaction.

Newcastle-on-Tyne, May 3rd.

DUBLIN.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS.

THE annual election of office-bearers will take place on the first Monday in June, and canvassing for the Council has already commenced. I have four names before me who seek election at the hands of the Fellows—viz., Messrs. Kendal Franks, Heuston, Norman, and Ward. Mr. Franks made such a satisfactory attempt last year, being defeated by only four votes, that I regard his success on this occasion as assured. This will be Mr. Heuston's first application, and although it is extremely unusual for a gentleman to obtain a seat on the Council on his first candidature, yet I think he will be well supported, and deservedly so. As regards Mr. Norman, who is resident medical superintendent to the Richmond Lunatic Asylum, he will, I am informed, if elected, devote special attention to matters affecting psychical medicine. Mr. A. H. Corley, vice-president, will succeed Sir William Stokes as president, and the office he vacates will be contested by Mr. Henry Fitzgibbon and Mr. H. Gray Croly. Both these gentlemen will be well supported, and the contest, I am convinced, will be a very close one.

THE VICTORIA JUBILEE HOSPITAL.

A committee was appointed last February for the purpose of taking steps to commemorate Her Majesty's Jubilee in a manner which would include the inauguration of some

Digitized by Google

work of public utility, and which would especially benefit the working classes of the county and city of Dublin. After due consideration, it was decided that the foundation of a hospital for consumption and diseases of the chest would be the most fitting memorial. The committee state that they were aware that persons suffering from consumption and other similar forms of lung disease cannot be treated with a fair prospect of success in town hospitals, and that in many cases it is inadvisable to admit such to the general hospitals of the city. By the establishment of a hospital of the kind proposed adjacent to Dublin, many patients may be successfully treated who at present end their days in the Hospital for Incurables, and many others, not absolutely curable, may be so alleviated as to enable the sufferers to lead comparatively healthy and useful lives. From the mortality returns of Ireland, it appears that over one-tenth of the deaths are caused by consumption, and about one-sixth by other diseases of the lungs; while in the city of Dublin and its immediate suburbs the annual average deaths from consumption number a little over 1000, from other diseases of the respiratory organs over 1800, the two groups forming about one-third of all the deaths which take place in Dublin. It is gratifying to state that the subscriptions towards the proposed hospital have already reached a sum of £6640.

DUBLIN HOSPITALS COMMISSION.

In addition to the remarks made in last week's issue relative to this report, there are a few others to which attention may now be directed. The commissioners, having reviewed the circumstances of each institution, make some suggestions which they consider will render them more effective institutions for the advancement of medical knowledge. They refer to the large number of small hospitals in Dublin, which add largely to the "establishment charges," and by frittering away the number of beds among so many hospitals, thus diminish the opportunities for clinical instruction. They recommend a reduction in the number of general hospitals, and believe that the total income of the various hospitals, taken at an average of £65,000, would suffice to support 1249 beds, the number maintained in 1884–5, if judiciously distributed among a few large institutions; but under the present circumstances the withdrawal of the Parliamentary grant would be attended with disastrous consequences. They suggest that the annual grants be commuted for a capital sum to be invested in the hands of trustees, and that the interest be paid periodically to a central board, to be distributed by them among such hospitals as shall fulfil certain specified conditions. In my opinion, it is extremely unlikely that these recommendations of the commissioners will be carried out; and, indeed, if they were in their entirety, it might prove injurious to some institutions which thoroughly deserve the grants they at present receive.

ACADEMY OF MEDICINE.

By a clerical error it was stated last week that the title of the Academy was intended to be "The Royal Irish Academy of Medicine"; it should have been stated that it was resolved to apply for permission to use the prefix "Royal," so that it shall be called "The Royal Academy of Medicine in Ireland."

THE "KENNEDY DEFENCE FUND."

Allusion has already been made in these columns to the groundless accusations brought against Dr. Kennedy, the resident surgeon of Mercer's Hospital. A committee has been formed, who invite subscriptions from the profession so as to express their determination to support one another when called on to meet charges arising out of the conscientious discharge of their duties, and also to indemnify the member of the profession so charged against law costs.

Dublin, May 3rd.

BELFAST.

(From our own Correspondent.)

THE BELFAST DISTRICT LUNATIC ASYLUM.

IN the fifty-seventh annual report of this asylum, just issued, Dr. Merrick, the able and courteous superintendent, states that there have been 196 admissions during the year, which, with those already in the asylum at the end of 1885, makes the total number under treatment 766; 130 have been discharged, and 35 have died, leaving a total of 601 in residence at the end of the year 1886. Of those discharged, seven were unimproved or harmless, forty-two were improved, and eighty-one recovered. One death occurred from suicide. The general sanitary condition of the house has been most satisfactory, and no case of infectious disease occurred. The gross expenditure for the year amounts to £12,837, which gives the cost per head at £21 14*s.* 4¾*d.*, and is a decrease of £1 4*s.* 4¼*d.* on comparison with the cost of the preceding year. Considerable changes in the *personnel* of the medical staff have taken place. Dr. Purdon has been appointed visiting and consulting physician, in place of Dr. Henry MacCormac deceased. Dr. W. Graham, assistant to Dr. Merrick, has been appointed medical superintendent of the Armagh Asylum, and Dr. Samuel Graham has been appointed in his place.

THE ROYAL HOSPITAL.

The summer session commenced on Tuesday, and the medical classes have also started at Queen's College. At the Royal Hospital Mr. John Campbell has gained the Coulter Exhibition, while the Malcolm Prize has been awarded to Mr. Quarry. Mr. Campbell has also won the Gold Medal at the Belfast Hospital for Sick Children.

MEETING OF SOCIETIES.

At the last meeting of the Ulster Medical Society, instead of the reading and discussing of papers, the evening was devoted to the exhibition of patients, instruments, and specimens. A large number of members of the Society were present, and among the contributors were Dr. Whitla, Dr. Esler, Dr. Dill, Dr. Sinclair, Dr. M'Caw, Dr. Browne, and Mr. Fagan. At the meeting of the North of Ireland Branch of the British Medical Association, held last week in Belfast, papers were read by Dr. Burden, Dr. Byers, Dr. O'Neill, and cases shown by the last-named gentleman and Dr. Esler.

AUSTRALIAN NOTES.

(From our own Correspondent.)

SANITATION (?) IN BRISBANE.

THIS town is in a very discreditable state, as far as health matters are concerned. There is a Central Board of Health, the members of which are Government nominees, who (with the notable exception of Dr. Taylor, who not long ago furnished the Government with a full report on the relative merits of different sewage systems, and who does all he can to stir the Board up) are content to do little but meet and take their guinea a sitting each. Certainly they have no powers entrusted to carry out any improvement, and have recently failed even in getting the Arcade cesspits removed, which are an acknowledged nuisance to the neighbourhood, and have to be emptied fortnightly by men going down into them and baling the excreta out in buckets. There is no permanent medical officer of health to the corporation, and the water supplied to the town by the Board of Waterworks was so filthy recently that one of the reservoirs had to be shut off on account of the general popular outcry against it.

HORRIBLE ABORTION CASES IN NEW ZEALAND.

Dr. Russell of Christchurch (a coloured American practitioner), who has been in practice in that town for some years, is now on his trial for abortion in three cases. The evidence goes to prove that he has been making a systematic practice of this, and he seems to have kept a sort of abortion hospital at a small boarding-house in the town, where he regularly attended. One woman who had been aborted by him acknowledged to having been twice operated on by him, and that on the former occasion the fœtus was put on the fire alive to destroy it. Another woman gave evidence that she had been aborted twice by him, had had criminal intimacy with him, and that the second pregnancy was by him. Ten pounds seems to have been his customary fee for the business. When arrested he endeavoured to commit suicide by taking tincture of aconite, but a dose of apomorphia administered hypodermically defeated his intention.

MEDICAL MEMBERS OF PARLIAMENT IN NEW SOUTH WALES.

There has been a dissolution of Parliament in New South Wales recently, and several medical men have obtained seats in the new House; I will give you their names in my next, as the

Digitized by Google

elections are not all concluded. Charles Kinnaird McKellar, M.B., one of the ablest medical men in Australia, was given a portfolio in the late Ministry as Postmaster-General, and was also Minister of Mines. He was chief medical adviser to the late Government, and I do not know where the present Government will find one to replace him if he goes out with the Ministry from that capacity.

SYDNEY AND ADELAIDE HOSPITALS.

The annual report of the Sydney Hospital shows that 2808 cases were admitted during the past year, 1091 being accident cases. The directors are £10,000 overdrawn at the bank, and a new building, estimated to cost £60,000, is considered essential. The report of the Adelaide Hospital shows 1878 admissions during the year, with a daily average of 174; deaths 164. Expenditure for the year £9679. The Government will expend £3000 in improvements and alterations.

MEDICAL PRACTICE IN QUEENSLAND.

I see that a correspondent (a "poitrinaire") asks what are the prospects of practice in Queensland. Queensland, like all the other Australian colonies, is pretty well as much overdone as England with respect to the supply of medical men, and their ratio to the population is even more than the English average. Thirty-one new men have started practice in Brisbane in the last five years. Of course, a good man does well in any town in Australia, but not better, I should say, than elsewhere.

MELBOURNE UNIVERSITY APPOINTMENTS.

At a meeting of the University Council in January, Mr. Baldwin Spencer was appointed to the chair of Biology; Dr. Springthorpe to that of Therapeutics, Dietetics, and Hygiene; J. B. Kirkland, Demonstrator of Chemistry; and J. W. Barrett, Demonstrator of Histology. At the February meeting the principle of admitting women to degrees in Medicine was adopted and referred to the Faculty of Medicine.

POISONING BY ANTIMONY IN NEW ZEALAND.

A man has just been condemned to death for poisoning his father-in-law by antimony early in 1886. He was sentenced to penal servitude for life for the attempted murder of his wife, by tartar emetic long administered in her food, and suspicions having arisen after his conviction for that offence, the body of his father-in-law was exhumed, and ample evidence was obtained by analysis that all the viscera were saturated with tartar emetic.

TYPHOID.

This is very prevalent in Victoria at present, but Queensland usually tops the list for the mortality from this disease, though with a much smaller population. Brisbane contributes largely to the sum total of that colony. As writers in the papers here freely point out, typhoid was almost unknown in Brisbane. Now typhoid is the third largest cause of fatality in Queensland. Last year a great many horses suffered from it in Brisbane.

COOKTOWN (QUEENSLAND) HOSPITAL.

This hospital is now over-full, crowded out mostly with fever and other patients from the Bloomfield Tin Mines, and as most of these patients do not belong to the district they are a serious strain on the finances of the hospital, which is in very straitened circumstances.

RAILWAY AMBULANCE CORPS IN NEW SOUTH WALES.

This movement is being carefully and energetically carried out under medical officers appointed by the Railway (State) Medical Board, and at a recent meeting of the corps, medals and certificates were presented to railway employés for proficiency in "first aid."

SALE OF POISONS ACT IN TASMANIA.

A new Act has just been passed in Tasmania to regulate the sale of poisons, which contains a sensible and practical regulation, taken, I believe, from the Canadian Act. Every poison sold is to have a written or printed label containing particulars of the antidote for such poison.

CONSUMPTION HOSPITAL IN MELBOURNE.

A movement is on foot to start an institution of this nature for Victoria, and undoubtedly it would be a boon on account alone of the number of cases ordered out from England to be cured by the Australian climate.

A steamer from China (the *Chingtu*) has landed a small-pox patient at Port Darwin in the northern territory. He is now convalescent, and the cargo, after being fumigated, was released.

The Intercolonial Medical Congress is progressing well. Dr. Verco having been appointed president and Dr. B. Poulton honorary secretary.

March 1st, 1887.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an extraordinary meeting of the Council held on Thursday, the 5th inst., the minutes of the last meeting were confirmed.

It was referred to the Library Committee to report on the filling of the vacancy caused by the decease of Mr. Chatto, librarian.

The President reported that Sir James Paget had consented to deliver the first lecture on Cancer and Cancerous Diseases.

It was agreed that diplomas be forwarded to those candidates who passed the recent examination in Surgery.

A report, dated April 2nd, 1887, from the committee of delegates of the Royal College of Physicians of London and of the Royal College of Surgeons of England, on the question of the grant by the two Colleges of degrees in Medicine and Surgery, was read, and, after discussion, was referred for further consideration.

A report, dated April 27th, 1887, from the President, senior Vice-President, and Mr. Marshall, on the purposes to which the unoccupied ground on the Embankment belonging to the two Colleges can be applied, was read, and referred to the Committee on the Extension of the College Premises to report thereon.

It was resolved that the Secretary be instructed to prepare an official abstract of the petition for the new Charter, and that the same, when completed, be issued to any Fellow or Member applying for the same. *Notice will be given when this is ready.* The Council do not think it expedient to convene a general meeting of the Fellows and Members of the College to consider and discuss the proposed draft of the Charter, the subjects to which it relates having already been submitted to previous meetings of Fellows and Members.

The picture of the Council in 1884-5, by Mr. H. J. Brooks, was presented by Sir T. Spencer Wells, on behalf of the subscribers to it, and accepted by the Council with thanks.

A letter of the 18th ult., signed, on behalf of the students of the London Hospital, by Mr. F. Howard Taylor, and forwarding a resolution adopted by the students in favour of the grant by the two Colleges of the degree of "M.D. Westminster," was read and referred to the Committee of the two Colleges.

A letter of the 30th ult. was read from the Secretary to the Science and Art Department, South Kensington, offering, through the Secretary of State for Foreign Affairs, to furnish to the Austro-Hungarian Government the name of any delegate whom the Council may wish to nominate to attend the International Congress on Hygiene to be held in Vienna in September next; and Sir T. Spencer Wells was nominated by the Council accordingly.

Obituary.

LEON GOSSELIN.

BY the death of Professor Gosselin, which occurred on the 29th ult., after a long and painful illness, French surgery has lost one of its most eminent representatives. M. Gosselin took his degree at the age of twenty-eight; the following year he was successful at the *concours de l'agrégation*, and in 1846 became Director of Practical Anatomy at the School of Medicine. Twelve months before he had gained the position of Surgeon to the Paris Hospitals, in which capacity he was successively attached to the Lourcine, Cochin, Beaujon, La Pitié, and La Charité. In 1858 he was named to the chair of Surgical Pathology, which he occupied until the death of Velpeau, whom he succeeded in 1867 as Professor of Clinical Surgery. Elected a member of the Academy of Medicine in 1860, and of the Academy of Sciences in 1874, in the place of Nélaton,

Digitized by Google

Gosselin had attained all the distinction which French science has in its gift. But a crowning honour was reserved for the close of his life, and a few months before his death he was called by the Academy of Sciences to its presidency. Professor Gosselin leaves a number of works upon medical and surgical science. Amongst these may be mentioned "L'Ostéite Epiphysaire des Adolescents," "Leçons sur les Hernies Abdominales," the "Compendium de Chirurgie," different memoirs on Septicæmia, Purulent Infection and Urinary Fever, V-Fractures of the Tibia, Tarsalgia of the Young, &c., but his *chef-d'œuvre* is his "Clinique de l'Hôpital de la Charité," a work which ranks justly with Trousseau's "Clinique de l'Hôtel Dieu."

JOHN MOORE, M.D.

IT was with deep regret that the Belfast public learned on Tuesday of the death of Dr. John Moore. The sad event occurred on Monday, May 2nd, at the Strathearn Hydropathic Establishment, Crieff, Perthshire, under exceedingly melancholy circumstances. For some months past the deceased gentleman had been in very poor health, suffering from mental depression; indeed, he seems never to have recovered the shock of his son's death, which took place about a year back. A week since, acting under medical advice, he left town for a complete change to Crieff. On Sunday evening, it seems, he retired to his room at his usual time, and in the morning was found dead in bed. The unfortunate gentleman had evidently committed suicide, the instrument used being a penknife, which was found beside him. During his brief stay at Crieff Dr. Moore had become known to several of the other visitors in the establishment, but, in spite of his very depressed condition, no danger was apprehended. Dr. Moore took his medical degree in 1851, being one of the first to graduate in the Queen's University. After this he was appointed dispensary medical officer in Glenarm, co. Antrim, and after residing there for several years he removed to Belfast, and was ppointed one of the surgeons to the Royal Hospital, a post he held for sixteen years; and since that he had been a consulting surgeon to the charity. He was also a life governor. He was surgeon to the co. Antrim Gaol, a post which is now at the disposal of the Government. Dr. Moore was the founder and first secretary of the North of Ireland Branch of the British Medical Association, and, also, a few years ago was president. He afterwards became the secretary, a post he held at the time of his death. When, in 1884, the British Medical Association visited Belfast, Dr. Moore was one of the local secretaries. He was also an active member of the Ulster Medical Society, of which at one time he was president, and for a long time he was medical officer to the Tyrone Fusiliers. He was among those who established a centre in Belfast for the St. John Ambulance Association, and for a time acted as secretary. The deceased took an interest in all charitable and philanthropic movements. He was one of the members of the Throne Hospital Committee, and was closely connected with the Young Men's Christian Association (of which he was one of the oldest vice-presidents) and the Prison Gate Mission. He was also local and honorary secretary to the British and Foreign Sailors' Society. Dr. Moore leaves a widow, three daughters, and a son, with all of whom sincere and deep sympathy is felt in their very sad bereavement, and especially with one of his daughters, who accompanied him to Crieff, and who was placed in a most sad and painful situation among those who were comparative strangers.

W. TIFFIN ILIFF, M.D. LOND.

WE record with much regret the death of Dr. William Tiffin Iliff, who was in practice for more than forty years—succeeding his father, Dr. W. T. Iliff, in 1863—at Newington-butts, South London. He was appointed medical officer of health for Newington in the year 1856, and retained the office with perfect satisfaction to the authorities until his death (a period of thirty-one years). Born at Newington in January, 1824, his education was commenced at Shrewsbury, whence he proceeded to Guildford, and afterwards to King's College, London. He entered at Guy's Hospital about 1841, passed successfully through his career, taking medals &c., became a Member of the College of Surgeons and Licentiate of the Apothecaries' Society in 1845, M.B. Lond. in 1855, and M.D. in 1856. He was hon. surgeon to the 7th Surrey R. V., and surgeon to the Royal South London Dispensary. His death took place on April 25th, after six weeks' illness, from extensive disease affecting the pylorus. He was a skilful practitioner, and esteemed as the kind friend of his patients as well as their medical attendant; and the poor of his district have lost a trusted and sympathetic helper, who was always ready to aid them in their time of need.

At the meeting of the Newington vestry on the 27th ult. an intimation was received of the death of Dr. Iliff. A resolution was unanimously adopted recording the vestry's appreciation of the deceased gentleman's services during thirty-one years as medical officer, and expressing sympathy with his family.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed all the necessary examinations were at an extraordinary meeting of the Council on the 5th inst. admitted Members of the College:

Andrews, Frederick William.
Arnison, W. Drewett, M.B. Dur.
Bacot, W. Rickward, L.S.A.
Baldwin, Harry.
Ballance, J. Descarrieres, L.R.C.P.
Barker, Alleyne, H., L.R.C.P.L.
Barr, Horace Carlos, L.R.C.P.L.
Barrett, Edward Ernest.
Barton, Francis A., L.R.C.P.L.
Batchelor, Charles, L.R.C.P.L.
Bishop, Charles Rosser, L.S.A.
Blurton, John Frederick.
Bowden, Ernest Edward, L.S.A.
Bower, William G., L.R.C.P.L.
Brackenbury, H. B., L.R.C.P.L.
Brook, William F., L.S.A.
Brooke, Charles Edward.
Browne, Robley Henry John.
Burke, H. Morton, L.R.C.P.L.
Burt, Cyril Cecil Barron.
Carter, Robert James, L.S.A.
Caudwell, Eber, L.R.C.P.L.
Chilcott, Arthur E., L.R.C.P.L.
Clarke, A. E., L.K.Q.C.P.I.
Cockill, W. Baron, L.R.C.P.L.
Connolly, F. Glynn, L.R.C.P.L.
Cox, A. H. Lissant, L.R.C.P.L.
Coy, W. Filmer, M.D. Kingston.
Dalgliesh, John W., L.R.C.P.L.
Dane, Robert, L.S.A.
Davenport, Cecil J., L.R.C.P.L.
Davies, Hughes Reid.
Ellison, E. Henry, M.A., L.S.A.
Farrar, Reginald Anstruther.
Fox, George Martin.
Fox, S. C. Gundry, L.R.C.P.L.
Gardner, Ernest F., L.R.C.P.L.
Garman, E. C., L.R.C.P.L.
Giddings, George Thomas.
*Goodman, Roger N., L.R.C.P.L.
Goodwin, F. C., L.R.C.P.L.
Gowan, Bowie Campbell, L.S.A.
*Green, Conrad T., L.R.C.P.L.
Greig, Duncan McBean.
Hallilay, Richard Percy, L.S.A.
Hamel-Smith, Lionel.
Harris-Liston, Llewellyn, L.S.A.
Harrison, Henry Leeds.
Hensley, Arthur Egerton, L.S.A.
Hinnell, Joseph Squier, L.S.A.
Hosegood, Samuel Price, L.S.A.
Hudson, Henry, L.R.C.P.L.
Hutton, John, L.R.C.P.L.
Iddon, Thomas Whittaker.
*James, Arthur William, L.R.C.P.
Jaques, John Warren, L.R.C.P.
Joseph, Arthur Hill.
Kerans, Felix.
King, Preston, L.S.A.
Labey, Julius, L.R.C.P.L.
Lankester, Francis J., L.R.C.P.L.
Lawrence, Thomas Wm. Pelham.
Lumley, Charles Armstrong.
McLean, W. W. Laroche, L.S.A.
McLurg, John, M.D. Toronto.
McVety, A. F., M.D. Kingston.
Marston, Henry John, L.R.C.P.
Megginson, Mowbray.
Metzgar, Charles, L.R.C.P.L.
*Miley, Miles, L.R.C.P.L.
Mould, William T., L.R.C.P.L.
Naumann, John C. F., L.S.A.
Osmond, Edward B., L.R.C.P.L.
Parry, Wm. T., M.D. Toronto.
Parsons, Charles O., L.R.C.P.L.
Paul, Arthur E., L.R.C.P.L.
*Peake, W. Pemberton, L.R.C.P.L.
Penno, Francis F. L., L.S.A.
Pitcairn, John James, L.R.C.P.L.
Pratt, William Sutton, L.S.A.
Pullan, H. N., L.K.Q.C.P.I.
Pye, Thomas, L.R.C.P.L.
Rees, John Morgan.
Roberts, Shirley, L.K.Q.C.P.I.
Robson, R. Barker, M.B. Durh.
Rutherford, John V. Walton.
Sharman, J. S. W. R., L.R.C.P.L.
Short, James Joseph, L.S.A.
Shute, G. Sidney, L.R.C.P.L.
Sidebotham, E. J., M.B. Cantab.
Skill, James Maurice.
Smith, Arthur H., L.R.C.P.L.
Smith, E. S., L.R.C.P.L.
Somerset, Edward, L.S.A.
Stokes, F. Wm., L.K.Q.C.P.I.
Stuart, Thomas E., L.R.C.P.L.
Swyer, Robert, L.S.A.
Thompson, W. H., M.D., Q.U.I.
Todd, H. B., L.R.C.P.L.
Travers, A. Lindsay, L.R.C.P.L.
Turnbull, George Lindsay.
Turner, Ernest Blaker.
Tweed, E. R., L.R.C.P.L.
Venis, Walter, L.S.A.
Vincent, H. E., L.R.C.P.L.
Vinter, S. Garratt, L.R.C.P.L.
Waites, R. F., L.R.C.P.L.
Walker, Benjamin, L.S.A.
Wallis, Maurice B. Arnold.
Ward, John Alfred, L.S.A.
Wedgwood, Wm. B., L.S.A.
Wheeler, James Atkin.
Whiston, Philip H., L.R.C.P.L.
Wigglesworth, V., L.R.C.P.L.
Wight, John Cam, M.B. Melb.
Williams, William, L.S.A.
Woods, Ninian Wildridge.

* Candidates under the Regulations of the Examining Board in England.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 30th ult., the following degrees were conferred:—

BACHELOR OF MEDICINE.—Frank Edward Nichol, Gonville and Caius; William John Hill, Jesus.

BACHELOR OF SURGERY.—Frank Edward Nichol, Gonville and Caius.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the April Examination the following candidate was admitted a Licentiate:—

Barnes, Ernest W., L.K.Q.C.P.I., Liverpool.

The following candidate obtained the qualification in Public Health:—

Kiddle, Walter, M.B. Dub., Surgeon, Medical Staff.

The following candidate having passed the full Exami-

Digitized by Google

nations for the Fellowship, was admitted a Fellow on the 2nd inst.:—

Dalziel, Thomas Kennedy, M.B., C.M. Edin., Regent-terrace, Glasgow.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At recent examinations the following were admitted Fellows of the College:—

Curran, Francis G. Adye, A.M.S. | Sawyer, R. H. Stewart, A.M.S.

COLLEGE OF PHYSICIANS IN IRELAND.—At the April examinations the following obtained licences in Medicine and Midwifery of the College:—

MEDICINE.—Patrick Hallon Fox, Bartley Hynes Hopkins, Edward Stewart Lewer, Joseph Maguire, A. Kennedy Forbes McCutcheon, Samuel McKee, Thomas Alexander Murray, Humphreys Robert Peare, Michael Riordan, Shirley Roberts, Nelson Cameron Sclater, William Thomas Steele, James St. Johnston, Jabez Davenport Wardle.

MIDWIFERY.—Edward Stewart Lewer, Joseph Maguire, Samuel McKee, Humphreys Robert Peare, Shirley Roberts, William Thomas Steele, and Jabez D. Wardle.

The under-named have been admitted Fellows:—

W. Beatty. | E. McDowel Cosgrave.
Alexander Duke.

SOCIETY OF APOTHECARIES.—The following gentlemen, having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates entitling them to practise as Licentiates of the Society on April 28th:—

Bowden, Ernest Edward, Gorsefield, Patricroft.
King, Preston, Barton-place, Bury St. Edmunds.
Rees, John Morgan, Machynlleth.
Short, J. J., Shortlands, Spencer Park, Wandsworth Common.
Somerset, Edward, Newbury, Berks.
Stephens, Richard John, Woodlands, Old Charlton.

OXFORD UNIVERSITY. — Dr. Brooks has been appointed Lichfield Clinical Lecturer in Medicine, and Mr. Horatio Symonds Lichfield Clinical Lecturer in Surgery, each for two years.

THE LEVEE.—John Sherburn, Esq., M.B., C.M., in his capacity of Sheriff of Kingston-upon-Hull, was present at the *levée* held at St. James's Palace on the 25th ult.

THE ROYAL SOCIETY.—Amongst the candidates selected by the Council to be recommended for election into the Royal Society are Dr. W. R. Gowers and Dr. J. T. Cash.

THE proceeds of the recent ball at the Brighton Royal Pavilion, in aid of the funds of the local Hospital for Women and Children, amount to £31.

NATIONAL HEALTH SOCIETY.—The annual general meeting of the Society was held at 44, Berners-street, on the 2nd inst. The report showed a great increase in the number of health lectures given in poor districts in London during the past year.

MEDICAL MAGISTRATE.—The Lord Chancellor, upon the unanimous recommendation of the Town Council and the Borough Bench of Magistrates, has placed the name of Mr. Vincent Jackson upon the Commission of the Peace for Wolverhampton.

PRESENTATIONS. — On the 23rd ult. Mr. O. B. Shelswell was presented by the officers of the Holborn Union Infirmary with an electro-plate tea and coffee service, on the occasion of his resigning his post as assistant medical officer at that institution, to take an appointment under the same Board of Guardians, at their new workhouse at Mitcham.——On the 26th ult., Mr. E. T. Ash was presented by his colleagues on the staff of the Brighton Dental Hospital with an illuminated address, on the occasion of his leaving England for South America.——In recognition of Mr. H. B. Vincent's services as a lecturer, the East Dereham members of the various classes in connexion with the St. John Ambulance Association have presented him with a hall clock and some volumes of medical literature, and the ladies of the Gressenhall class have also presented him with a handsome ivory paper knife.——At a meeting of students of the Charing-cross Hospital, held on Thursday last, in the Board-room, a testimonial was presented to H. Montague Murray, M.D., M.R.C.P., on the occasion of his marriage and in recognition of his services as medical registrar during the last five years. The testimonial was presented by Mr. C. P. Oliver, and took the form of a clock of the time of Henry II., being copied from the catalogue of the Archæological collection of Prince Soltykoff.

DR. EDWARD PALMER, the medical superintendent of the Lincoln County Asylum, having, after thirty-nine years' services, sent in his resignation, the Visiting Committee have submitted a recommendation to the Quarter Sessions of Lindsey, Kesteven, Holland, and the Town Councils of Lincoln, Stamford, and Grantham, to award him a superannuation allowance of £600 per year.

ANNIVERSARIES OF BELGIAN MEDICAL SOCIETIES.—The Antwerp Medical Society has recently held a grand meeting in honour of the fiftieth anniversary of the Society's foundation. The mayor of Antwerp and Professors Lefebvre, Van Beneden, Dumoulin, Boilée, and Thiry were present at the banquet.—The Belgian Society of Public Medicine has just celebrated its tenth anniversary, under the presidency of M. Kuborn. There was a theatrical entertainment and meetings of various sections. At the grand final meeting the King and his suite and the Minister of the Interior were present.

UNIVERSITY OF LONDON.—The following Examiners for 1887-88 were elected at a meeting of the Senate on the 27th ult.:—Chemistry: Prof. J. Emerson Reynolds, M.D., F.R.S., and Prof. W. A. Tilden, D.Sc., F.R.S. Botany and Vegetable Physiology: Prof. Bayley Balfour, M.D., D.Sc., F.R.S., and Prof. F. Orpen Bower, M.A. Comparative Anatomy and Zoology: Prof. E. Ray Lankester, M.A., F.R.S., and Adam Sedgwick, M.A., F.R.S. Practice of Medicine: William Cayley, M.D., and Prof. F. T. Roberts, M.D., B.Sc. Surgery: W. Morrant Baker, Esq., and Prof. Christopher Heath. Anatomy: Prof. D. J. Cunningham, M.D., C.M., F.R.S.E., and Prof. John Curnow, M.D. Physiology: Prof. E. A. Schäfer, F.R.S., and Prof. Gerald F. Yeo, M.D. Obstetric Medicine: F. H. Champneys, M.A., M.B., and John Williams, M.D. Materia Medica and Pharmaceutical Chemistry: J. Mitchell Bruce, M.D., M.A., and T. Lauder Brunton, M.D., D.Sc., F.R.S. Forensic Medicine: Prof. G. V. Poore, M.D., B.S., and Thomas Stevenson, M.D.

QUEEN'S COLLEGE, BELFAST.—The following is the official list of the results of the medical examinations in April:—Anatomy and Physiology: Third Year—J. M. Hall. Second Year—S. A. Powell, B.A.; H. L. Atkinson, B.A.; James Fulton; Robert Forsyth. First Year—John Jamison; Douglas Maconachie. Practical Anatomy: Third Year—J. M. Hall; R. C. McCullagh, B.A., and D. C. Smiley, equal; James Buchanan; C. E. Shaw, M.A.; James Hunter. Second Year—James Fulton; S. H. Withers; James M'Connell and Nathaniel Morton, equal. First Year—(J. S. B. M'Murray, non. mat.); K. B. Barnett; James Adrian; (W. A. Collier, non. mat.). Medicine: Second Year—John Campbell, M.A.; R. C. M'Cullagh, B.A. First Year—Robert Wilson and M. H. Quarry, equal; Robert Thomson. Surgery: Senior—John Campbell, M.A., and James Hunter, equal; R. C. M'Cullagh, B.A.; C. E. Shaw, M.A. Junior—J. M. Hall; Robert Wilson; M. H. Quarry. Materia Medica; Nathaniel Morton; W. H. Cox; H. J. Anderson; James Fulton. Midwifery: D. C. Smiley; Robert Thomson; Robert Wilson and C. E. Shaw, M.A., equal. Practical Chemistry: John Jamison and E. W. M'Bride, equal; Nathaniel Morton. Zoology: G. S. Hart; Andrew Fullerton; Thomas Jackson.

SCHOLARSHIPS AND PRIZES.—At the *London Hospital Medical College*, the hospital scholarship, value £20, for proficiency and zeal in clinical medicine, has been awarded to Mr. C. R. Killick, and an honorary certificate to Mr. Benjamin Walker; the hospital scholarship, of the value of £20, for proficiency and zeal in clinical surgery, to Mr. Evelyn Oliver Ashe, and honorary certificates to Mr. Owen Meredith Jones and Mr. Benjamin Walker; and the Duckworth-Nelson prize in practical medicine and surgery, value £10, to Mr. Benjamin Walker, and an honorary certificate to Mr. Owen Meredith Jones. — At the *Middlesex Hospital Medical School*, the Broderip scholarships, of the value of £30 per annum and tenable for two years, has been awarded to Mr. W. H. Vickery, and that of £20 per annum, tenable for two years, to Mr. E. E. Lewis.—At *St. Thomas's Hospital Medical School*, the William Tite scholarship of £30 has been awarded to Mr. Henry Burden; the Musgrove scholarship, of £42 per annum, tenable for two years, to Mr. Arthur Francis Stabb; the second tenure of the Peacock scholarship to Mr. Francis Charles Abbott; the Mead medal to Mr. W. W. Ord; and the Cheselden medal and the Treasurer's gold medal for general proficiency and good conduct to Mr. Frank Fawssett.

OPHTHALMOLOGICAL SOCIETY.—A special meeting of this Society is to be held on June 23rd for the purpose of collecting facts in reference to toxic amblyopia. Communications, whether written or *vivâ voce*, which bear on the subject will be acceptable. Facts in elucidation of the following points are particularly desirable:—1. Cases of true alcoholic amblyopia—i.e., failure of central vision in drinkers who do not use tobacco in any form. 2. Cases of recovery from any form of toxic amblyopia—e.g., from tobacco, bisulphide of carbon, &c.—without complete discontinuance of the toxic agent. 3. Cases of complete persistent pallor of the optic disc consequent on a long-continued exposure to any of these forms of poisoning. 4. Do second attacks of central amblyopia ever occur, whether induced by the original agent or by any other?

HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S-PARK.—The annual meeting of this institution was held on Wednesday at the Eyre Arms Assembly-rooms. The report, the adoption of which was moved from the chair by General Maclagan, R.E., laid stress on the great need of funds generally prevailing among the London hospitals, and congratulated the supporters that the debt had only increased £60 during the past year. He expressed the hope that the "jubilee" which marked among the Jews a time for "setting free" from bondage would be characterised by a similar liberation of the hospitals from the "bondage of debt." The Right Rev. Bishop Perry seconded the motion. The reappointment of the retiring members of the committee was moved by Sir W. Magnay, Bart., who said that the administration by his colleagues of the funds at their disposal was a far easier task than the collection of funds to administer. Mr. R. B. Chapman alluded, as a regular visitor to the wards, to the distressing nature of the diseases treated in the hospital, and to the great need of such an institution.

MEDICAL NOTES IN PARLIAMENT.

The Prevention of Rabies and Hydrophobia.

IN the House of Lords on the 29th ult., Lord Mount-Temple called attention to the regulations for the prevention of rabies and hydrophobia. He considered the present method of muzzling both injurious to the dogs and inefficient for the purpose of preventing the spread of the disease. The principle upon which he had proceeded in framing his Bill was to place a responsibility upon the owner of the dog, who should have presented to him such a statement of the premonitory symptoms of rabies as were set forth in one of the Orders issued by the Agricultural Department of the Council. In addition to the present register of persons who had paid the dog tax and obtained a licence, there ought to be a register of the dogs themselves as well as of the owners. When the tax was paid, he proposed that there should be given to the owner of the dog a badge bearing a number, which should be placed on the collar of the animal. This number being registered, could always be seen; and if a dog was found wandering about in the streets or roads without a collar, it would be *primâ-facie* evidence that the animal was ownerless, when it might be taken up by the police. The Bill did not propose to interfere with any of the existing regulations, but placed it within the power of the authorities to add the method of registration he had described and placing responsibility upon the dog owner as an alternative for the muzzle.—Lord Cranbrook thought the ordinary powers only required to be put in force to stamp out rabies. In 1885 there were not less than seventy-five cases of rabies in the metropolitan area, and besides that twenty-eight people died of hydrophobia in and close to London. Muzzling was enforced, and the number of cases immediately fell. The best authorities were of opinion that the disease might be stamped out altogether by a universal system of muzzling.—The Earl of Kimberley hoped the authorities in the metropolis and throughout the country would not be deterred by any outcry that might be raised against the muzzling of dogs from doing what was possible to stamp out the disease.—The Bill was read a first time.

The Cold Bath for Lunatics.

In the House of Commons, on the 3rd inst., Dr. Kenny asked the Chief Secretary, with reference to the case of "Lamb *v.* Ashe," tried recently before the Recorder of Dublin, under what rule of Privy Council or order of Lunacy Department the use of the cold plunge bath was permitted as a punishment for lunatics.—Colonel King-Harman said the use of the cold plunge bath for curative purposes had been sanctioned under a rule of the Dundrum Asylum, but the Irish Government had now given orders for its discontinuance.

Impure Water-supply.

In reply to Mr. Norton, Mr. Forwood stated that a long report had been received with reference to the supply of impure water to Her Majesty's ships at Malta, resulting in a serious outbreak of enteric fever, and that the tanks were periodically tested and cleansed.

Public Sanitation.

Mr. F. Powell gave notice that on an early date he would introduce a Bill to amend and extend the Public Health Act of 1875, and to consolidate the statutes relating to the public health which had been passed since that year.

Leave to introduce the Temporary Dwellings Bill was obtained on Wednesday. It has for its objects the education of gipsy and van children and the bringing of sanitation into their homes.

BOOKS ETC. RECEIVED.

BAILLIÈRE, TINDALL, & COX, King William-street, Strand, London.
Brief Statement of the so-called "Salisbury Plans" of Treating, by Alimentation. By J. H. Salisbury, M.D. pp 64.
A Manual of Veterinary Hygiene. By Fred. Smith, M.R.C.V.S. pp. 475, Illustrated.

CHURCHILL, J. & A., New Burlington-street, London.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BELL, THEODORE, B.A., M.B., B.Ch.Dub., has been appointed Medical Officer to the Morchard Bishop District of the Crediton Union.

CARPENTER, G. ALFRED, M.B. Lond., has been appointed Resident Medical Officer to the Evelina Hospital for Children, vice Albert Martin, M.D.Lond., resigned.

COOK, THOMAS D., M.S., C.M.Glas., has been appointed Medical Officer for the Torquay District of the Newton Abbot Union.

DYER, BERNARD, B.Sc., F.C.S., has been appointed Public Analyst for the City of Truro.

ESSOR, HENRY C., M.R.C.S., L.S.A., has been appointed Surgeon to the Cardiff Eye and Ear Hospital.

FOX, E. L., M.A., M.B., B.C.Cantab., M.R.C.S., has been appointed Senior House-Surgeon to the Liverpool Children's Infirmary, vice Francis Johnston, resigned.

GOODALL, JOHN K., L.R.C.S., L.R.C.P.Ed., has been reappointed Medical Officer of Health for the Bolsover District of the Chesterfield Union.

GRANT, DAVID, M.A., M.B.Edin., has been appointed Lecturer on Materia Medica, Medical Botany, and Elementary Therapeutics in the University of Melbourne.

GREEN, R. W., M.R.C.S., has been appointed House-Surgeon to the Leeds General Infirmary.

HARTLEY, HORACE, M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Workhouse and for the Stone District of the Stone Union.

NICHOLSON, C., M.R.C.S., has been appointed House-Surgeon to the Leeds Infirmary.

PARRY, JOHN WILLIAM, L.R.C.P., L.R.C.S.Ed., L.F.P.S.Glas., has been appointed Surgeon to the Bettisfield and Coleshill Collieries, Bagillt.

PEAKE, JOSEPH, L.F.P.S.Glas., L.S.A., has been appointed Medical Officer for the Parish of Falkirk, vice Hadden, deceased.

PEARCEY, JAMES J. W., L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Howden District of the Auckland Union.

PRICE, ARTHUR, M.R.C.S., L.S.A., has been appointed Surgeon to Her Majesty's Prison at Winson-green, Birmingham, vice Waterton, deceased.

PRIMROSE, ALEXANDER, M.B., C.M.Edin., has been appointed House-Surgeon to the Paddington-green Children's Hospital, vice Leonard G. Guthrie, M.A., M.R.C.S., L.S.A., whose appointment has expired.

ROBERTS, WILLIAM LAKE, M.R.C.S., L.M., L.S.A., has been appointed Surgeon to the Bradford District of the Great Northern Railway.

TRAVERS, WILLIAM, M.D., F.R.C.S., late Senior Assistant Physician to the Chelsea Hospital for Women, Fulham-road, S.W., has been appointed Physician to that institution.

WARNER, F. A., M.R.C.S., L.R.C.P., L.S.A., has been appointed Surgeon to St. Gabriel's Hospital for Infants, Chelsea, vice J. Cantlie, F.R.C.S., resigned; also Assistant Medical Officer to St. John's Lying-in Home, Gunter-grove, S.W.

WILSON, FRANCIS, L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the North Keighley District of the Keighley Union.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BLACKBURN AND EAST LANCASHIRE INFIRMARY. — House-Surgeon. Salary £100 per annum, with board, washing, and lodging.

CHARING-CROSS HOSPITAL, Strand, W.C.—Assistant Surgeon. Medical Registrar.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead.—Two Clinical Clerks for the out-patient department.

HOSPITAL FOR WOMEN, Soho-square, W.—Clinical Assistants. Fee for course of three months, £5 5s.

LINCOLNSHIRE COUNTY LUNATIC ASYLUM, Bracebridge. — Medical Superintendent. Salary and emoluments £400 per annum, with furnished house, coals, gas, milk, vegetables, and washing.

LIVERPOOL STANLEY HOSPITAL.—Senior House-Surgeon. Salary £80, with board, &c.

MADAGASCAR MEDICAL MISSION. — Superintendent of Hospital &c. Salary £150 to £200 a year, house, outfit, &c.

MASON SCIENCE COLLEGE, Birmingham.—Professor of Physiology.

NATIONAL DENTAL HOSPITAL, Great Portland-street, W. — Assistant Dental Surgeon:

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury. — Senior House-Physician. Salary £100 per annum. Junior House-Physician. Salary £50 per annum. In each case board and apartments are supplied in the hospital.

ROCHDALE INFIRMARY AND DISPENSARY.—Resident Medical Officer. Salary £80 per annum, board, &c.

ROYAL ALBERT HOSPITAL, Devonport. — Assistant House-Surgeon. Board and lodging in the hospital, but no salary.

STAFFORDSHIRE GENERAL INFIRMARY, Stafford. — Assistant House-Surgeon. Board and lodging, but no salary.

ST. MARY'S HOSPITAL, Paddington, W.—Physician in charge of out-patients.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—Lecturer on Systematic Physiology.

TEIGNMOUTH, DAWLISH, AND NEWTON INFIRMARY AND CONVALESCENT HOME.—House-Surgeon and Dispenser. Salary £71 per annum, with board (beer excepted), lodging, and washing.

WEST SUSSEX, EAST HANTS, AND CHICHESTER GENERAL INFIRMARY AND DISPENSARY.—House-Surgeon and Assistant Secretary. Salary £100 a year, with board and rooms.

Births, Marriages, and Deaths.

BIRTHS.

BROWN.—On the 16th ult., at Penang, the wife of Wm. Carnegie Brown, M.D., of a son.

CHIPPERFIELD.—On the 21st ult., at Bloxam, the wife of Pearse Chipperfield, L.R.C.P., M.R.C.S., of a daughter.

GREENWOOD.—On the 1st inst., at High-street, Clapham, the wife of C. D. Greenwood, M.R.C.S., of a son.

HABERSHON.—On the 1st inst., at Upper Wimpole-street, W., the wife of S. Herbert Habershon, M.B.Cantab., M.R.C.P.Lond., M.R.C.S., of a son.

MILNE.—On the 26th ult., at Accrington, the wife of Thomas Milne, M.A., M.D., of a son.

PENFOLD.—On March 17th, at Sandhurst, Victoria, the wife of O. Penfold, M.R.C.S., L.S.A., of a daughter.

MARRIAGES.

CARTER—JONES.—On the 27th ult., at St. Peter's Church, Bournemouth, W. Fitzwilliam Carter, L.R.C.S.I., L.R.C.P.Ed., to Florence Archer, daughter of John Averay Jones, Esq., J.P., of Vale House, Clifton.

COTES—ALLINGHAM.—On the 30th ult., at St. George's, Hanover-square, Charles E. Cotes, M.B.Cantab., to Elizabeth Christiana (Lily), elder daughter of Wm. Allingham, of Grosvenor-street, W.

DAVENPORT—SIEVWRIGHT.—On the 28th ult., at Holy Trinity Church, Hobart, Tasmania, Arthur Frederick Davenport, M.B.Lond., M.R.C.S., of St. Kilda, Melbourne, to Alline, daughter of the late Major Allan Sievwright, Royal Artillery.

FRITH—FARNCOMB.—On the 28th ult., at Hollington Church, Baptist Gamble Frith, B.A., M.B., B.Ch., to Georgina Anne, eldest daughter of Edward Farncomb, Esq., of Ashbrooke-park, Hollington.

GARSON.—ASPINALL.—On the 20th ult., at Bebington Parish Church, W. R. J. Garson, M.B., to Emmeline, fifth daughter of Clarke Aspinall, Esq., J.P., and Coroner of Liverpool.

MILES—KING.—On the 28th ult., at Melbourne, Victoria, Geo. H. Miles, M.R.C.S., L.R.C.P.Lond., to Ada Louise, youngest daughter of the Rev. Richard King, formerly of Prestwich.

PARSLOE—RAY.—On the 28th ult., at Holy Trinity Church, Worthing, Henry Heath Parsloe, M.R.C.S., L.R.C.P., to Emily Ann, daughter of Henry R. Ray, Heine-terrace, Worthing.

SNOW—JARRETT.—On the 20th ult., at St. Matthew's Church, City-road, London, Lionel Mason Snow, M.R.C.S., L.R.C.P. Lond., to Jennie, eldest daughter of Evan Jarrett, Esq., of Barnsbury-park, N.

WEST—JACOB.—On the 4th inst., at St. Peter's Church, Dublin, by the Rev. John Alexander Jacob, Rector of St. Saviour's, Bath, uncle of the bride, assisted by the Rev. Canon Jellett, and by the Rev. H. H. Noyes, M.A., Francis Robert Leighton, second son of the Rev. William West, Rector of Randalstown, Suffolk, to Florence Alice, eldest surviving daughter of Archibald Hamilton Jacob, M.D., F.R.C.S., of 23, Ely-place, and "Lucerne," Sandycove.

DEATHS.

FOX.—On the 3rd inst., at the Park Hotel, Preston, Wilson Fox, M.D.

HALKET.—On the 17th ult., at sea, on his homeward voyage from Australia, Laurence John Halket, L.R.C.P.Lond.

NOLLOTH.—On the 29th ult., at 13, North-terrace, Camberwell, Edward Nolloth, retired Fleet Surgeon, R.N., M.R.C.P., F.R.C.S., sixth son of the late John Nolloth, Esq., of 1, North-terrace, Camberwell, aged 73.

THOMPSON.—On the 29th ult., at Winterton House, Westerham, Kent, Charles Robert Thompson, M.R.C.S., aged 57.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, May 9.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.
SOCIETY OF ARTS.—8 P.M. Mr. J. M. Thomson: The Chemistry of Substances taking part in Putrefaction and Antisepsis.

Tuesday, May 10.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.
ROYAL INSTITUTION.—3 P.M. Prof. W. E. Ayrton: Electricity.
MEDICO-PSYCHOLOGICAL ASSOCIATION.—4 P.M. Quarterly Meeting. Meeting of Council at 2.30. Discussion on the proposed Lunacy Law Amendment Bill.
SOCIETY OF ARTS.—8 P.M. Mr. E. J. Tarver: The Architecture of London Streets.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Arthur E. Barker: A case of Intussusception of the Upper End of the Rectum due to Obstruction by a New Growth, Excision of the Intussusception, Suture of the Cut Ends of the Bowel, Complete Recovery.—Mr. Stanmore Bishop: Results of an Experimental Inquiry as to the Best Method of Restoring the Canal after Removing Portions of the Small Intestine (communicated by Sir Spencer Wells).

Wednesday, May 11.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M. Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M. Saturday, same hour.
SOCIETY OF ARTS.—8 P.M. Mrs. Ernest Hart: Cottage Industries in Ireland.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Dr. Maddox: On the Different Tissues found in the Muscle of a Mummy.
EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Dr. Arthur Ransome: Some Evidence respecting Tubercular Infective Areas.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown by Drs. Granville Bantock, Fancourt Barnes, Grigg, and others.—Dr. Routh: On the Various Modes of Treatment to be adopted for the Worst Cases of Uterine Flexions.

Thursday, May 12.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION.—3 P.M. Prof. Dewar: The Chemistry of the Organic World.

Friday, May 13.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
CLINICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Godlee: Some cases of Abdominal Cyst following Injury.—Dr. Vivian Poore: A case of Spasmodic Torticollis, probably due to Cerebral Lesion.—Mr. Stephen Paget: A case of Suppuration in a Chronic Gouty Knee-joint.—Mr. Spencer Watson: A case of Intra-capsular Impacted Fracture of the Neck of the Femur, with specimen. Living Specimens:—Mr. Clinton: Case of Osteitis Deformans in a Female, with Lengthening of some of the Bones.—Dr. Percy Kidd: Case of Rheumatic Nodules in an Old Woman.—Mr. Sydney Jones: (1) Case of Extirpation of Uterus for Fibroid, recovery (and the specimen); (2) A case of Tumour of the Bladder removed by Supra-pubic Operation (and the tumour).
ROYAL INSTITUTION.—9 P.M. Prof. J. S. Burdon Sanderson: Some Electrical Fishes.

Saturday, May 14.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION.—3 P.M. Prof John W. Hales: Victorian literature.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

RAVAGES OF WILD ANIMALS AND SNAKES IN BENGAL.

THE total number of persons killed by wild animals and venomous snakes in the ten divisions of Bengal during the official year 1885-86 was the highest in the last five years, and amounted to 11,823. As is usual, nine-tenths of these deaths were caused by snakes. But of 12,223 buffaloes, oxen, horses, and ponies destroyed in this manner, only 371 were killed by snakes. These annual returns do not take account of sheep, goats, pigs, and monkeys, the destruction of which is very large. Passing over the most formidable wild animals, it appears that 548 persons were killed by jackals, 291 by crocodiles or alligators, 84 by pigs, and 22 by elephants—whether wild or domesticated is not stated,—12 by buffaloes and oxen, 1 by a horse, 1 by a deer, and 2 by musk rats, the bite of the latter having been followed by mortification. Only 18 deaths were put down to mad dogs, which is regarded as a manifest understatement. Not a single death was caused by wild animals in the town and suburbs of Calcutta, but 13 persons died from snake-bite. The total amount of 29,884 rupees was paid for the destruction of wild animals and venomous snakes, as compared with 42,374 rupees in the preceding year.

H. M.—Our correspondent should consult the Medical Register; but we doubt in any event if he has a legal remedy.

Mr. J. H. Sykes is referred to a general notice at the head of this column.

STROPHANTHUS.

To the Editors of THE LANCET.

SIRS,—At this time, when Professor Fraser's elaborate experiments with strophanthus are bringing it to the fore in therapeutics, it is interesting to note that Dr. Livingstone, in the account of his 1863 expedition up the Shiré branch of the Zambesi river, mentions that Dr. Kirk, who accompanied the expedition, owing to carrying his tooth-brush in the same pocket with some of the kombi, or arrow poison used by the Ajawa and Manganja tribes, accidentally experimented on himself, and "though the quantity was small, it immediately showed its power by lowering the pulse, which at the time had been raised by a cold, and next day he was perfectly restored," and remarks that "it is possible that the kombi may turn out a valuable remedy." This case points to its value as a febrifuge. I am, Sirs, yours faithfully,

Clifton, May 2nd, 1887. CLEMENTS HAILES, M.D., C.M.

KENNEDY DEFENCE FUND.

THE honorary secretaries beg to acknowledge the following contributions to the above fund, which is being raised to pay the legal expenses incurred in refuting a cruel and groundless charge, particulars of which will be found in an advertisement in the present number of THE LANCET. The committee invite the co-operation of all members of the profession in promoting the defence fund, and request that subscriptions be forwarded to the honorary treasurer, Dr. M'Veagh, 1, Rutland-square East, Dublin.

Sir Prescott G. Hewett, Bt.	£5	5	0	William Bruce, M.D. ...	£1	1	0

Mr. J. de Courcy Young (Bruthen).—We do not see how we can help our correspondent.

Beta.—The course of action is quite legal, but very unwise.

"INHALATION OF COAL-GAS AS A SOURCE OF DISEASE."

To the Editors of THE LANCET.

SIRS,—Attention has been lately called to the deleterious effects produced on the human body by the inhalations of coal-gas in small quantities. The public, equally with the medical profession, are aware of the dangers to health resulting from the presence in respired air of this gas in sufficient volume to be appreciated by the sense of smell. How great is the sum of ill-health produced by this necessity of our civilisation is perhaps hardly realised, both on account of the insidiousness of the symptoms and the association of them often to causes other than the right one. In an introduction to "Our Homes," entitled "Health in the Home," written by Dr. Richardson, he tells how he himself suffered from symptoms due to the adulteration of the air of his library by carbonic oxide derived from the escape of coal-gas from faulty pipes in minute but toxic quantity. Nausea, giddiness, coldness of the body, and inaptitude for work led him at first to suspect stomach derangement. Noting, however, the similarity of the symptoms with those produced previously on himself while experimenting with carbonic oxide, he was led at last to the real source of the mischief. I remember soon after this article was published meeting a medical man who complained to me of drowsiness and giddiness, combined with coldness of the extremities and this same inaptitude for exertion. His digestion was excellent, his frame robust, and he was becoming seriously alarmed at what he thought might be indications of cerebral mischief. I told him that I felt sure he was suffering from carbonic oxide poisoning, and, to add weight to my words, gave him Dr. Richardson's article to read. Then the secret came out. His symptoms were always aggravated during the evening, after he had been sitting for some time in his dining-room, and his wife had also of late shown a drowsiness which was foreign to her habit. In this room a short time previously an indiarubber pipe had been fitted to the gaselier, to bring the gas down to a water-heating apparatus on the table, which was always used at this time of the day. The symptoms dated from the time of this fixture, and the connexion in my mind between the two things was complete. The diagnosis was rendered certain by my friend, who at once did away with the apparatus, telling me a few days afterwards that all unpleasant symptoms had passed away, and that he had never felt better in his life. This pertinent incident may help to call the attention of your readers still more to a source of danger to health which I have long felt to be as common as it is often unsuspected.—I am, Sirs, yours faithfully,

H. M. ELLIS, Staff Surgeon, R.N.

H.M.S. *Valorous*, Devonport, May 2nd, 1887.

Juvenis should write to the Secretary of the College, who will doubtless afford the information required.

BROWN DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Kindly permit me to acknowledge the following:—Amounts previously received, £13 1s. 6d. Dr. J. Broward Neal, 10s. 6d.; Dr. M. A. Ward (Dublin), £1 1s.; R. H. A. Hunter, Esq., £1 1s.; Messrs. Roby and Roby, £1 1s. I am, Sirs, yours faithfully,

G. STANLEY MURRAY.

Meadow Side, 23, Upper Richmond-road, Putney, May 4th.

THE CLIMATE OF COLORADO.

IN reference to an inquiry recently inserted in our columns, Mr. T. Laffan of Cashel sends us a letter, from which we make the following extract:—"I must say, from experience and a long residence in Colorado and the adjoining territories, that the climate is unsurpassed. To those suffering from incipient consumption, by proper attention to exercise, such as hunting, fishing, &c., there is no question but in a short time all traces of the disease will disappear. I have known young men who went there eight or nine years ago as hopeless invalids, and after a few months' sojourn returned to their eastern homes rugged and robust men. Those far advanced in consumption will have a hard time of it as regards breathing, owing to the extreme lightness of the atmosphere. For such the equable temperature of New Mexico is more suitable. As a resort I would recommend the San Louis Park; it is a beautiful valley, extending several hundred miles, running north and south from Del Norte Col to Santa Fé, New Mexico, and over twenty miles wide, between the Sangré De Christo and Conejos ranges of the Rockies, with an average of about 4000 ft. elevation by sea-level. Game abounds, and fishing in the Rio Grande river, which runs through the valley, is excellent. The winters are not quite so rigorous as in the mountains. I have seen men in that country who were so emaciated physically that their life was not worth a cent. Profuse expectoration appeared to trouble them most. In a short time they became hale and hearty. Persons in an advanced state or period of the disease suffer much; they even bleed from the nose and mouth on the least exertion. This is owing to the high altitude and light air. But the Mexican people say that by drinking tea made from the mild mountain sage all traces of the disease are eradicated; and no Mexican is troubled with consumption that is to be attributed to climatic influences."

Cyclops.—We consider the charges very reasonable. The legal profession would not consider itself remunerated on any such terms. Our correspondent would do well, however, to base his charges entirely on professional attendance, throwing medicine in, or charging little more than cost price.

Q.—A very full exposition of the subject of coma was published in the number of *Brain* for January last, from the pen of Dr. Mercier—an article which is well worthy of perusal.

P. W. should consult his medical attendant. We do not prescribe.

"SIMILIA SIMILIBUS CURANTUR."

To the Editors of THE LANCET.

SIRS,—Sin that I han ben ylogged in Hades mo than four hundred yeres, I pray you to be patient wid me, thanne wol I tell ye sikerly that which doth wirry me moche. Certes, ther is a very parfite practisour, ycleped Doctour Lauder Brunton, wel versed in ye causes of everich maladie and the werking of dragges. Eke hath he shewed you that ye conseils of Homœopathy be alway ful of errour, inasmuchel as they weren enforced willoin by the auctoritee of a persone, hight Hahnemanne. Douteles ther ne hath ben naught neue under the Sonne; but I n'am not desirous for to teche yonge men of hir practike. I wold only say that phisiciens at my daye wer used to sayn, "right as maladies ben cured by hir contraries, right so shal man warisbe werre," the which wordes I han writ in ye Tale of Melibee, as you mote se fer yourselven, if it so be that ye han gotten my werkes. Touching my letter, I beseke you of youre good will, for iche n'am not mochel used to dite letters sin I han ben here; and the postes gon selden time here abouten.

Youre servant in alle humblesse,

GEOFFREY CHAUCER
His Gost.

C. T.—The answer must be uncertain. The body named will only be able to grant a registrable qualification, *after the date mentioned*, in the event of other bodies combining with it, or the Medical Council appointing examiners in surgery.

Mr. T. B. Gibbs will find the method described in THE LANCET of April 16th last.

A. R. W.—The book mentioned is perhaps the best for the purpose.

OBSCURE NERVOUS AFFECTION.—OBESITY.

To the Editors of THE LANCET.

SIRS,—In reply to two correspondents in your last issue, one signing himself "Puzzled" and the other "Subscriber," I would suggest a trial of massage in both the cases to which they respectively refer. The neuropathic condition developed by the patient of the former would, in my opinion, judging especially from the history of the case, be much benefited, if not entirely cured, by such a process; and with regard to obesity, as referred to by the latter, one case has lately been brought under my notice in which under a course of massage the patient lost seven inches round the hips and five inches and a half round the waist in three weeks.—I am, Sirs, yours faithfully,

R. A. DOUGLAS LITHGOW, M.D., M.R.C.P. Ed., &c.

Lowndes-street, S.W., May 3rd, 1887.

Digitized by Google

A GIANT AMONG GIANTS.

THERE are giants and giants. There are even giants among giants; and we venture to say that the Austrian giant now to be seen in London is one of these. He is most phenomenally tall. Though twenty-two years old he is thought to be still growing, and has certainly grown an inch or more in the last nine months. He has three sisters and one brother. Neither in them nor in his family has there been any instance of undue height. It is said that he was not unusually tall until the age of fourteen, when he began to shoot upwards.

Etiquette.—The rule mentioned cannot be always applied. The special circumstances of the case must be taken into consideration, or injustice may unwittingly be inflicted.

M. W.—Only graduates of universities are entitled to the prefix.

"DANGERS OF SWING-BOATS."

To the Editors of THE LANCET.

SIRS,—In Leicestershire a similar case to that recorded in your last issue came under my care last autumn, a young child having been struck on the left side of the forehead by an iron screw-nut on the bottom of a swing-boat. A portion of the frontal bone, about an inch long, was firmly fixed into the base of the skull, and two portions of convolutions were mingled with the débris. Unsuccessful efforts under chloroform were made to extract the bone, and the whole treated with a weak solution of perchloride of mercury. The child lived fifty hours, and until two hours before death, in spite of the gravity of the injury, there was neither severe hæmorrhage, paralysis, unnatural pupil, loss of speech, nor vomiting. Death was preceded by strabismus, convulsions, and syncope. I am, Sirs, yours obediently,

Skipton-in-Craven, May 2nd, 1887. C. W. SESSIONS BARRETT, M.B.

ERRATUM.—In Dr. Nesfield's letter published last week, page 904, the date of the premature labour was inaccurately given as Oct. 5th. It should have been Dec. 5th.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Harkin, Belfast; Dr. De Watteville, London; Dr. Bristowe; Sir W. Mac Cormac, London; Dr. Hollis, Brighton; Dr. Fothergill, London; Mr. Lawson Tait, Birmingham; Dr. G. Macdonald, London; Mr. Edmund Owen, London; Dr. Cheadle, London; Mr. J. Startin, London; Mr. Simeon Snell, Sheffield; Mr. Tempest Anderson, York; Dr. Weaver, Southport; Mr. J. Oliver, London; Mr. Graham, London; Mr. Marmaduke Sheild, London; Dr. Sadler, Barnsley; Mr. C. A Clinical Lecture

ON THE

PATHOLOGY AND TREATMENT OF LARYNGISMUS, TETANY, AND CONVULSIONS,

ILLUSTRATED BY CASES OF THESE DISORDERS IN CHILDHOOD, AND ALSO BY A CASE OF THE TETANY OF ADULT LIFE.

BY W. B. CHEADLE, M.D., F.R.C.P.,

SENIOR PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, PHYSICIAN AND JOINT LECTURER ON MEDICINE TO ST. MARY'S HOSPITAL.

(Concluded from page 981.)

THE next point of importance, and one of the first moment to us as physicians, is the cause. What gives rise to tetany and the allied conditions, laryngismus and convulsions? Let us take the case of adults first. Trousseau styled the affection the rheumatic contraction of nursing women. This arose from the fact that the first few cases which he saw were all in women who were suckling; and he deemed the affection rheumatic probably because of the pain and swelling of the extremities, really due to the pressure of muscular cramps, and because exposure to cold appeared to be the exciting cause. Subsequent experience led him to modify this view, and he acknowledged many conditions as predisposing. Another antecedent supposed to be almost invariable was diarrhœa. In Trousseau's cases diarrhœa was almost invariably present. He gives one case, however, in which the bowels were obstinately constipated. In ten cases of adults I have found recorded elsewhere, diarrhœa was noted in two only, as absent in four, and in the remaining four not noted. Then another point. In all nineteen cases together—Trousseau's and others—twelve were in women. Of these twelve, seven were suckling, two were pregnant, and one had had several miscarriages recently. Four of these had diarrhœa, and two menstruated while suckling. Tetany comes on in adults also as a sequel to acute specific fevers, especially in cholera and typhoid fever, in which diarrhœa is a prominent symptom. In the vast majority of cases, then, if not in all, tetany supervenes in patients whose nutrition is impaired by drain or flux—that of lactation or pregnancy, or diarrhœa or hæmorrhage.

Let us take now the case of children, and see whether the conditions which favour the occurrence of the disorder in them are in any degree similar. In the first place, the affection in nearly every instance occurs in children under three years of age—the period of rickets, the period of dentition. In the second, in every instance which I have seen the child has also had well-marked rickets. In every one of the fourteen cases collected by Dr. Abercrombie there was marked rickets. Further, in every instance which I have seen the tetany was associated with the first spasmodic disorder—viz., laryngismus. In all Dr. Abercrombie's cases there was likewise accompanying laryngismus. Now, according to my observations, laryngismus is invariably associated with rickets.[1] Again, the third spasmodic disorder is associated with rickets—viz., general convulsions[2]; and a considerable proportion of these cases of tetany and laryngismus suffer from convulsions. Therefore in children spasmodic disorder in these three forms—viz., laryngismus, carpo-pedal contractions or tetany, and general eclampsia—are essentially associated with the rachitic condition. This is, indeed, the key to the subject. The constitutional state in rickets in children, fruitful of tetany and all kinds of convulsion, is closely analogous to the constitutional state in which tetany is apt to occur in adults. Rickets, remember, is not mere defective nutrition of bone, but defective nutrition of *all* structures—of muscle and nerve, as well as of bone. It arises largely on a diet of starchy food—i.e., not by the evil effects of starch and sugar, but because the diet is deficient in animal albuminates and animal fats. It arises frequently, too, where nutriment is drained off by frequent and long-continued vomiting and diarrhœa. Sometimes, again, in a condition closely allied to it, as the result of the cachexia of congenital syphilis. In the child, then, as in the adult, the constitutional state which predisposes to spasmodic disorder is subnormal nutrition. This state is, however, brought about in a different way in the two cases. Children get into the state which favours laryngismus, tetany, or convulsions when the nutrient milk is not given, or its equivalent of animal albuminates and fat. The nursing mothers get into the state which produces tetany from loss of the same nutriment in the milk they yield. In the case of children the fault of insufficient supply is constantly aggravated by the drain of diarrhœa or vomiting. In the case of adults the fault of drain by flux of milk or diarrhœa is frequently aggravated by insufficient supply. The condition of nervous system which renders it so unstable, this hyper-excitability, would appear to be due to defective nutrition of motor cells. Their protoplasm is as ill-nourished as we know the nitrogenous element of muscle to be in like cases. Look at the myoidema of wasting diseases. Muscle is hyper-excitable in this condition; nerve centre is hyper-excitable likewise. There is no affection of the governing cerebrum, for there is no affection of the sensorium, but an undue excitability of the motor ganglia of the cord; probably no permanent organic change.[3] This is perhaps not all. There is an immediate exciting cause; the reflex irritation of diarrhœa, or teething, or exposure to cold, or indigestible food. But the constitutional defect is the essential antecedent, the predisposing cause underlying all, rendering the nervous organism morbidly sensitive to slight irritation. As in the strychnia-poisoned frog, tetanic symptoms may not be developed if it remains quiescent, but the stimulus of a shake or jar brings on a convulsive seizure. Now, gentlemen, I lay stress upon these points of etiology and pathology, because they bear so strongly upon treatment, and this is of vast importance. The disease, indeed, involves little risk to life in the case of adults. I know of two cases only on record in which the disease proved fatal.[4] With children, however, the case is otherwise. They do not die of the tetany, but they do die of laryngismus and convulsions, sometimes of concurrent exhausting diarrhœa, or bronchitis, or catarrhal croup. The majority get well, but now and again death occurs. So long as the condition of excessive irritability of the motor nervous system evidenced by the carpo-pedal contraction and attacks of laryngismus remains, so long is the child in danger from spasm of the glottis, fatally prolonged, or the supervention of general convulsions.

Treatment.—In the olden time treatment was chiefly divided towards relieving a supposed congestion of the brain and cord. Trousseau relied upon bleeding for this purpose in tetany, and claims great success for it. He also gave quinine, opium, belladonna, and chloroform inhalations. Yet his claim to success seems hardly borne out by the evidence. In the case of one woman who died, bleeding aggravated the symptoms, the muscles of respiration became affected, and asphyxia appeared imminent. Twelve leeches were then applied behind the ears, but before they had fairly taken the patient succumbed. In the case of a man also who had tetany in the most severe form, bleeding from the arm, repeated several times, was followed on every occasion by increased contractions involving the muscles of respiration and threatening asphyxia. Cupping along the spine, however, appeared to give decided relief, and the patient recovered, possibly in spite of the treatment rather than in consequence of it. But, indeed, bleeding, in persons already exhausted by drain or deficient nutriment as these patients are, would seem to be the very worst therapeutic measure possible. We know, moreover, that loss of blood in quantity tends to produce the convulsive state. Animals bled to death die convulsed; animals starved to death sometimes die convulsed. In the case of these poor debilitated, rickety children, bloodletting, even in the mild form of

[1] Dr. Gee found this fault—viz., rickets—in 48 out of 50.

[2] Dr. Gee noted general convulsions in 19 out of 50 cases of laryngismus.

[3] In a fatal case of mine (examined by Dr. Abercrombie) the brain and membranes were healthy, the medulla and cord seemed rather firmer than usual, and the grey matter, if anything, too pale. No other change in any organ. Langhaus (quoted by Abercrombie), in a fatal case in a man aged forty, found some changes, especially in the anterior white commissure of the cervical enlargement—viz., thickening of the tunica adventitia of small arteries and veins, due to the presence of lymphoid cells in the reticulated stroma. (Is this the result of congestion set up by convulsion?) The affection is transient; it is not *a priori* likely that it depends on permanent organic changes.

[4] Trousseau's case, and that of Langhaus noted by Abercrombie.

Digitized by Google

leeching or cupping, is out of the question. The practice is based upon a pathological error.[5] The condition of the nerve centres is really one of anæmia already, not of congestion.

The objects to be sought in the treatment of tetanoid laryngismal convulsive disorder of childhood are threefold—(1) to relieve dangerous convulsive seizures when they occur, (2) to ward off these attacks from recurring, and (3) to remove the constitutional rickety state which predisposes to them. For the first purpose:—In laryngismus, a dash of cold water in the face, a hot sponge to the larynx, a finger in the throat to induce the act of vomiting, are approved methods to unlock the dangerous spasms. In general convulsions, the vapour of chloroform may be given between the seizures, or ten grains of chloral and twenty grains of bromide may be given by injections into the rectum, or from one to three grains of chloral in solution injected hypodermically in an urgent case. The latter I have tried once only, but with an excellent effect. It is often impossible to give medicine by the mouth, and a hypodermic injection acts more quickly and more certainly than one into the rectum. For the second purpose (i.e., to ward off attacks) give chloral and bromide. Each good, but best both together. They have a marvellous power, chloral especially, in averting tetany and laryngismus, and probably in preventing general convulsions. They must be given in fairly full doses and at regular intervals of sufficient frequency, so that the system is kept constantly under their influence. For a child of six months, half a grain of chloral to one or two grains with three of bromide every four hours. For one a year old, from one to three grains of chloral with five grains of bromide every four or six hours, and so on in proportion. Children bear chloral well. Dr. Wilks gave to a boy three years old with tetany ten grains of chloral three times a day with the best effect. Bouchut gave thirty grains to children of two to five years, sixty grains to children of seven years, to produce anæsthesia for operation. I should not hesitate to give much larger doses than those I have indicated should urgent symptoms arise. In one case of severe tetany in a boy of two years, in which chloral (two grains) and bromide (five grains) given every four hours failed to produce improvement, I gave one-twelfth to one-fifth of a grain of Calabar bean with good effect. With larger experience I should try much larger doses of chloral in a similar case before resorting to Calabar bean. Let me give, however, this warning with regard to the free use of bromide and chloral. Bromide in five-grain doses every four hours for some days occasionally produces severe pustular rupial eruption. Chloral at most induces drowsiness, therefore rather push chloral than bromide in case of necessity. This treatment by sedatives may have to be continued in greater or less degree for weeks and weeks, until the tendency to spasm permanently declines. Thus gaining time by keeping the nervous system in safe quiescence, you proceed to treat the rickety state, the evil condition which underlies and is the prime source of all. For this purpose give milk, cream, or raw meat if milk cannot be borne, with the best kinds of infants' food, or entire wheat flour (rich in phosphates and nitrogenous matter); later, cod-liver oil and syrup of lacto-phosphate of lime or of lime and iron. Another useful adjunct in increasing nutrition and aid in increasing blood flow to the anæmic nerve centres in these cases is brandy, half a drachm to a drachm, given in half an ounce to an ounce of food every four or six hours. It has also another advantage: it acts on children chiefly as a sedative and narcotic, and produces no excitement. And I must enforce the paramount importance of this full nutrient treatment, because there is a common and grave error pervading practice in these cases—viz., that of adopting a spare and lowering diet, such as barley-water, weak broths, and arrowroot. Such had been the medical advice given in the second case which I related: a most pernicious plan, against which I wish to protest as strongly as possible—the remnant of the old idea that the morbid condition at the root of the disease was one of plethora and active congestion, instead of debility and anæmia. Moreover, many confound a full nutritious diet with an indigestible irritating diet. Raw meat, for instance, is not indigestible; it is most digestible as well as most nutritious—i.e., the soft pulp scraped free from the fibre; and so with cream. A spare, thin diet, such as veal broth, barley-water, and arrowroot, is no more digestible, and infinitely less nutritious. Let me repeat, then, that the food should be as digestible and nutritious as possible, with a high proportion of animal albuminates and fats. Then, again, this evil of low diet in these cases is constantly heightened by the over-use of strong purgatives and depressant drugs: aiding artificially the very condition of draining off of nutriment and deficient vitality we know to be the prime fault of the disorder. If the immediate exciting cause of convulsion be the irritation of undigested food, a dose of castor oil should of course be given at once; or if there be obstinate constipation, sufficient doses of some simple laxative, such as magnesia, may be given to relieve it, or a single dose of calomel may be useful on occasion. But the free and frequent use of strong purgatives does nothing but harm. Lastly, if diarrhœa be present—and you will remember that it is an almost constant accompaniment of the rickety and tetanoid state—it must be controlled. For it is injurious in two ways: (1) by draining off nutriment from the alimentary canal before there is time for it to be absorbed, and (2) by the reflex irritation it sets up. For the relief of diarrhœa bismuth is one of the best remedies. It should be given in the form of the insoluble trisnitrate, and in full doses; the doses usually given are far too small to be really effective: four or five grains every four hours to a child six months old, and more in proportion to age, and with it a quarter of a drop of laudanum, or the castor-oil mixture of the Hospital Pharmacopœia, one, two, or three drachms every four hours, with a quarter to one drop of laudanum according to age; or, if there be sickness with the diarrhœa, from half to one grain of grey powder, with from a quarter to half a grain of Dover's powder, according to age, may be given every four hours; or a mixture of chalk and catechu with hæmatoxylum and small doses of tincture of opium, if the alvine discharges are watery and profuse. But astringents are less valuable than drugs like bismuth, chalk, and the sedative opium.

[5] Experiments show that convulsive seizures and spasm (apart from organic disease, such as meningitis, tumour, &c., or poisoning) are produced by two causes chiefly: (1) carbon products in blood—venosity; (2) anæmia of nerve centres. Kussmaul and Tenner (see Stirling and Landois, vol. ii., p. 901) found the spasm centre in the medulla could be excited by (*a*) suddenly producing a highly venous state of blood, either by asphyxia or by compressing the veins coming from the head, or (*b*) by sudden anæmia of the medulla, either in consequence of hæmorrhage or ligature of the carotids and subclavians. In all these cases the stimulation of the centre is due to the sudden interruption of the normal interchange of gases.

Lectures ON INJURIES OF NERVES.

Delivered at the Royal College of Surgeons,

BY ANTHONY A. BOWLBY, F.R.C.S. ENG.,
SURGICAL REGISTRAR AND DEMONSTRATOR OF SURGICAL PATHOLOGY AT ST. BARTHOLOMEW'S HOSPITAL, HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS.

LECTURE II.

TROPHIC CHANGES CAUSED BY NERVE INJURY.

MR. PRESIDENT AND GENTLEMEN,—In addition to the partial or entire loss of sensation and motion in the parts supplied by the divided nerve, the various tissues are liable to undergo changes which are chiefly of a degenerative nature, though sometimes combined with inflammatory conditions. The extent to which these changes are dependent on a want of nerve force will be left for future consideration, and for the present it will be sufficient to study the morbid processes themselves. The first authors to draw attention to the altered nutrition of the parts supplied by a divided nerve were Hilton in his lectures on Rest and Pain (p. 199), and Paget in the *Medical Times and Gazette* of March, 1864; but since then they have widely occupied the interest of surgeons, and it would be impossible to allude here to all the writers on this subject, amongst whom the names of Charcot, Weir Mitchell, and Hutchinson occupy the foremost places. It must first of all be premised that many of the changes to be described, which will be known once for all as "trophic changes," are not by any means the invariable sequel of nerve section, but rather that, instead of such conditions being the rule, some of them are the exception.

The skin.—The condition of the skin most characteristic of nerve lesion is a smooth shiny-red appearance, generally known by the name of "glossy skin." The description of Paget in the *Medical Times and Gazette*, already alluded

Digitized by Google

to, yet remains the most graphic. He says: "In well-marked cases the fingers which are affected (for this appearance may be confined to one or two of them) are usually tapering, smooth, hairless, almost void of wrinkles, glossy, pink or ruddy, or blotched as if with permanent chilblains. They are commonly also very painful, especially on motion, and pain often extends from them up the arm. In most of the cases this condition of the fingers is attended with very distinct neuralgia, both in them and in the whole arm; and its relation to disturbances of the nervous condition of the part is, moreover, indicated by its occasional occurrence in cases where neuralgia continues after an attack of shingles affecting the arm. In two such cases I have seen this same condition of the fingers well marked and only very slowly subsiding, and seeming unaffected by the ordinary treatment of neuralgia."

Weir Mitchell,[1] while agreeing with Paget's description, also remarks that the epithelium is partially lost, and that the cutis is exposed in places, while the subcuticular tissues are wasted. The same author notes that "where a single nerve, as the ulnar, had been attacked, the described state of the skin was seen only in its ultimate distribution; but in other instances of more extensive nerve injury the central palm suffered, or a single finger, or the pulps of all of them. In others the palm or fingers were dotted with islets of thin, red, and glossy skin. The dorsum of the hand, as a rule, was in that member the part least subject to the alteration, while the dorsum of the foot was in that region the part most liable to suffer..... The state of the skin to which I refer is never present without burning pain, and commonly the earlier presence of this form of neuralgia enabled us to predict the coming of the skin disease. In no case did it become visible short of two weeks, but usually it preceded the healing of the wound, and not rarely was to be traced to an outbreak of inflammation involving the wound. The duration of the malady varied from a few weeks to years, but in all the cases I have been able to follow it has either been cured or gradually disappeared."

The foregoing descriptions mainly agree with my own observations. Weir Mitchell's statement, however, that this glossy skin is "never present without burning pain," admits, I think, of some doubt, and I question if the same condition is not sometimes permanent, despite his opinion to the contrary. Both of these points are illustrated by the following case.

W. H——, aged forty-two, divided his median nerve two inches above the wrist in August, 1870. On July 19th, 1882, I found the skin over the back and front of the two last phalanges of the index and middle fingers red, glazed, and tightly stretched, so that it could not be pinched up in the least; there was no appearance of any papillæ or of hair; the fingers as a whole were very thin and tapering. He had no pain of any kind except in very cold weather, when he said the affected parts caused a tingling sensation of "pins-and-needles." In this man, then, the glossy skin had existed twelve years, and as the patient assured me it showed no sign of improvement, we may fairly conclude that the condition was likely to remain permanent. In another case of an old man who had divided his ulnar nerve ten years previously, the skin over the little finger and part of the ulnar side of the palm remained glossy, yet without pain, except, as in the previous case, in cold weather.

In addition to the glossy condition just described, the skin is liable to various forms of eruptions, which may or may not occur coincidently with the above affection. Of these, undoubtedly the most common form is a vesicular rash, sometimes presenting an appearance very similar to herpes, but frequently occurring as large bullæ, such as are seen in pemphigus. As in the case of glossy skin, it is chiefly the parts at the extreme periphery of the nerve which are affected, and these in a most irregular manner. For instance, after division of the median nerve it is common to find any one of the three digits supplied by it the seat of a bulla, while the others are healthy. The earliest date after nerve section at which I have found the appearance of vesicles recorded is the second day. The case is detailed by Mr. I'Anson in the *Medical Times and Gazette* for Dec. 30th, 1871. Weir Mitchell saw the thumb rapidly covered on the fourth day by a large bulla, and "looking as if blistered." These eruptions are very common for some months after the primary lesion, but in cases where the section has occurred some years previously I have not met with them, nor do I find mention of them by other writers under similar circumstances.

In addition to the vesicular eruptions, Weir Mitchell describes an eczematous condition of the skin which he thinks is more frequently found than true herpes; and, indeed, it often becomes very difficult to give a name to a rash which is not quite like any that occurs under other circumstances. In some cases the inflammation of the skin is more intense, and results in the production of abscesses or ulcers. The former, which have been particularly described by Hutchinson under the name of "subcuticular whitlow," are most common, as their name implies, at the tips of the fingers; the pus in them is only covered by the upper layers of the skin, and the nail is sometimes destroyed; the course of the whole inflammation is, however, painless. The ulcers which are found at the tips of the fingers are frequently the result of a subcuticular whitlow, which has burst, and thus exposed the delicate papillæ, which, being free of all tactile sense, are constantly liable to irritation by surrounding objects. The ulcers thus formed sometimes proceed to the destruction of a considerable amount of tissue, and I have seen one case in which nearly the entire tip of the index finger and part of the middle were so eroded within five months of the accident. It must, nevertheless be borne in mind that many of the ulcers which follow nerve section owe their primary origin to some traumatism, and more especially to the effect of heat and cold acting on an anæsthetic part. In one case that came under my notice the man had burnt the end of his finger with a lighted pipe; in another, by carrying very hot plates; in a third, by touching one of the bars of a fireplace; and such instances could be indefinitely multiplied. In many patients, as pointed out by various authors, the ulcers heal with great readiness; but such is not always the case, more especially, I am inclined to think, where no traumatic origin was present as an exciting cause. In the case above mentioned of destruction of the tip of the index, the ulcer, after healing, again broke down, while the hand was completely protected from injury; and in another the ulceration was still present ten months after the division of the nerve, and slow to heal. In a few rare cases a whole finger or fingers become completely gangrenous. Hilton describes such a case in his work on "Rest and Pain," in which the two last phalanges of the fifth and the tip of the fourth finger were completely separated by a line of demarcation. The cause of this was an exostosis pressing on the ulnar nerve in the subclavian triangle and also causing occlusion of the subclavian artery. There can be no doubt that this plugging of the vessel would act as a predisposing cause, but, as Hilton justly points out, the whole of the hand was subjected to the same influence, though only those fingers supplied by the ulnar nerve suffered. A less equivocal case is that recorded by Mr. I'Anson, already alluded to. Here the median nerve was divided at the wrist in a man aged twenty-four on June 8th. Two days later vesicles and black patches appeared on the fingers, but improved under galvanism. On Aug. 11th bullæ again appeared, and were followed by gangrene of the whole index finger.

In the following case gangrene of a part of the hand followed on division of the ulnar nerve.[2] On Nov. 29th, 1881, N. P——, aged forty-seven, received a severe lacerated wound from a circular saw on the inner side of the forearm, dividing, together with other structures, the ulnar artery and nerve. The artery was tied, and the wound dressed with carbolised oil. The wound healed by December 24th. The patient was then discharged as cured, but returned on January 6th, 1882, with gangrene of the ulnar side of the hand extending into the little finger. The whole hand was œdematous. Finally, a slough about half an inch deep came away and the gangrene ceased to extend.

The nails and hair.—The nails and hair, as might be expected, share in the changes affecting the skin. While speaking of subcuticular whitlow, I have mentioned that the nail of the affected finger sometimes perishes, but the nails occasionally undergo other changes in shape and texture of a kind peculiar to nervous lesions. Judging from a considerable number of cases of such injuries that have come under my own notice, I should be inclined to consider characteristic changes in the nails as not very rare, although this opinion is unsupported by the almost complete absence of any mention of such diseased nails by other authors. Thus, of seven cases recorded by Hutchinson of divided

[1] Injuries of Nerves, p. 157.

[2] Root. New York Medical Record, 1882, p. 560.

Digitized by Google

nerves, in only one were the nails found to be "stumpy, broken, and uneven on the surface"; while other English surgeons have passed over the question in silence. Weir Mitchell, Morehouse, and Keen, however, in some patients noticed very considerable lesions. They say: "The alteration in the nail consists of a curve in its long axis, an extreme lateral arching, and sometimes a thickening of the cutis beneath its extremity. In other cases a change takes place which is quite peculiar, and which to us at least was new. The skin at that end of the nail next to the third finger-joint becomes retracted, leaving the sensitive matrix partly exposed. At the same time the upper line of union of skin and nail retreats into or under the latter part, and in place of a smooth edge is seen through the nail a ragged and notched border. The patient who presented these changes in the most striking form had also lateral arching of the nail, but no longitudinal curving. It was a case of most terrible suffering from a combination of burning pain in the hand and neuralgic pain in the forearm. No deformity of nails in tubercle at all approaches that which nerve wounds occasion. Indeed, we think it would be possible for one familiar with these cases to diagnose the existence of a nerve lesion from the form of these protuberant and oddly curved nails. When the nails of the toes have been attacked, and they are very rarely so, the curving is less marked; but a distressing ulceration is apt to occur at their angles, and to break out again and again, despite of every care and attention. In many cases of nerve wounds, where there is only ordinary neuralgia, and not glossy skin and causalgia, I have seen the nails clubbed in some places, and in others dry, scaly, cracked, and fragile. Occasionally they are very thin, so as to be tender—atrophied, in fact. ..... Even complete nerve section does not prevent lost nails from being re-formed."

In the above graphic description, however, the authors do not mention in what proportion of cases they observed such lesions, or whether they occurred as a rule in recent divisions or in those of later date. It has appeared to me that after nerve section there may be simply a diminution in the rapidity of growth of the nail, combined with a stunted and fibrous appearance, or else that changes of a more special nature such as those described above may be observed. Of eleven cases of old injury which I examined consecutively, in only one was there any stunted and fibrous appearance of the nails. The other ten patients exhibited no morbid changes whatever, and for the most part expressed their opinions that the nails of the one hand grew as rapidly as did those of the other. In ten consecutive cases of more recent nerve section, within a year of the accident eight patients showed no change in the nails, but in the two others the latter presented a very strange and characteristic appearance, in many respects resembling the description by Weir Mitchell.

The first patient was a boy aged fourteen, who had sustained a division of the median and ulnar nerves nearly a year previously. The nails of all the fingers were short, stumpy, and broken, excessively arched both longitudinally and transversely, with transverse furrows and ridges running across them, the latter being marked with a delicate longitudinal striation, giving them a "toothed" appearance. The nails were thick and not tender, and the surrounding skin was not retracted from their bases. The patient said that they had been in this condition ever since a few weeks after the accident; he thought they grew as rapidly as those on the opposite hand.

The second patient was a lad, aged seventeen, who had divided the median nerve five months previously, and in whom partial union had resulted, and was still progressing. The nails of *all* the fingers and thumb presented conditions very similar to those just described, except that the nails were very long—a condition, combined with their extreme curvature, which gave them a talon-like appearance. In this respect the thumb nail differed from its fellow, being short and only half grown; this was accounted for by the fact that the nail had been painlessly shed from this digit a month previously, and had not yet grown. The patient said that all the nails grew rapidly, and their appearance certainly warranted the statement.

These cases, and others that I have since seen, would tend to the belief that trophic changes in the nails appear soon after the nerve injury, as might be expected from the time at which similar lesions are found in other parts. Each patient had lost one nail entirely, a loss which may fairly be attributed to a more complete cutting off of trophic influences from this digit than from the others. In addition to the curvature, the most characteristic appearance was found in the peculiar striated or toothed condition of the transverse ridges, which was quite different to anything I had seen. In the last patient perhaps the most surprising fact was that, although it was quite certain that only the median nerve had been divided, the nails on the fourth and fifth fingers were quite as much affected as those of other digits. This peculiarity I have seen in other cases.

Changes in the hair growing in parts deprived of their nerve supply have appeared to me to be very common. In most of the cases I have examined, the hair, when any has been present, has appeared short, stumpy, and brittle. In some patients it was altogether absent, and, as has been remarked by Paget and Weir Mitchell, especially in cases of glossy skin. I have only once been able to obtain any portion of skin for microscopical examination, so as to see the exact conditions of the hair follicles, and found in it that the absence of the hair was accompanied by a corresponding degeneration of the follicle. In some rare exceptions, the growth of hair after nerve wounds has been very excessive. Weir Mitchell quotes several examples, but does not appear to have seen cases himself, and none have come under my own notice. Hamilton, however,[3] records a case in which a nerve appears to have been wounded in the operation of venesection, and in which symptoms of chronic neuritis ensued, the arm being subsequently covered by a rich growth of hair. The patient was a young lady.

The *connective tissues* deprived of their nerve supply usually undergo atrophy, and the palmar fascia sometimes shrinks and becomes indurated in a very noticeable manner. In some patients there is developed a great tendency to œdema, a condition which is probably due to section of some of the vaso-motor nerves. Weir Mitchell has described, in addition, cases where hypertrophy of the connective tissues was very marked, apparently the result of chronic œdema.

The *secretion of sweat* is in most cases more or less affected. By most of the patients I have seen in whom the injury was of some standing there was a tolerable certainty expressed that the parts deprived of their nerve supply were always dry. I examined some of them on very hot summer days, and in most of them the parts affected remained dry, while the rest of the hand was moist, and this despite energetic friction. In some cases, apparently those of partial division complicated by neuritis, the secretion of sweat has been described as excessive, and Weir Mitchell records cases in which it was very acid and foul-smelling.

Considering these facts by the light of recent researches in physiology, it might almost be said that such conditions would be only just what we might expect from nerve section or irritation; but it is interesting to note that they were observed before experiments had proved the dependence of the secretion on nerve supply.

The *temperature* of the paralysed parts often differs considerably from that of the opposite side of the body, of contiguous digits, &c. Immediately after section of a nerve—e.g., the median—the distal parts become suffused with blood, and appreciably hotter to the touch. Waller and Weir Mitchell have both shown that a similar rise of temperature follows on freezing the ulnar nerve at the elbow, and the latter observer has also demonstrated that this elevation does not occur if a tourniquet has previously been placed on the brachial artery,[4] thus showing the dependence on the vaso-motor system. This increased heat is well instanced in the following two cases:—

A man, aged thirty, divided his ulnar nerve on May 8th, 1885, and came at once to St. Bartholomew's Hospital, where the cut ends were sutured by the house surgeon, Mr. Murray. Eight hours after the accident the temperature taken between the fourth and fifth fingers was 100·2°, between the first and second, 99°.

	Between 4th and 5th fingers.	Between 1st and 2nd fingers.
May 10th	99·0°	98·0°
„ 11th	99·6	98·2
„ 14th	98·0	97·4
„ 15th	98·2	98·2
„ 16th	101·6	101·6
„ 18th	100·6	99·6
„ 19th	99·4	98·8
„ 20th	98·0	97·6
„ 21st	99·0	98·0

Speaking generally, the temperature of the paralysed fingers averaged about 1° higher than that of the others.

[3] Dublin Journal of Medical Science, 1838.
[4] Archiv of Sci. and Prac. Med., New York, 1872.

Digitized by Google

and this variation remained constant despite alterations in the general body temperature.

In the next case a woman, aged twenty-seven, divided her median nerve at the wrist. The following day the temperature between the index and middle fingers was 99°, whilst that between the ring and little finger was 96·6°; the day after, the temperature between the index and middle fingers was 98·8°, that between the ring and little fingers 97°.

The following case by Richelot[5] is a very remarkable instance of the rise of temperature that may follow on separation of peripheral parts from the nervous centres:—

Fracture of humerus followed by neuroma of median nerve; resection of nerve followed by rise of temperature in hand.—A man aged twenty-six was admitted to the hospital of La Pitié on Dec. 30th, 1882, on account of severe pains in the right forearm. His history was that at the age of seven years he had sustained a compound fracture of the lower end of the right humerus, and that the arm had always been in a weak condition and the elbow had been stiff. On admission there was found to be on a level with the site of fracture a small oval swelling the size of an almond, situated apparently on the median nerve. Pressure on the swelling caused pain referred to the thumb, index and middle fingers. In these fingers also sensation was much impaired. The muscles of the forearm and of the ball of the thumb were much wasted, but were not completely paralysed. The temperature of the hand on the affected side was 4·5° below that on the opposite side. On January 15th, 1883, Mr. Verneuil removed the tumour by operation, completely cutting out the portion of median nerve from which it grew, and not stitching the cut ends, but leaving them widely separated. The tumour itself was found to be a fibroma, separating the nerve tubules, and by its pressure destroying some of the nerve bundles. After the operation the temperature of the hand on the side on which the operation had been performed—i.e., the right—was 34°, of the left 30°. The day after the operation the temperature of the right hand was 35°, and of the left 25°. Sensation was still further lost, but was *nowhere entirely absent*. The further history of the patient is not given.

But although immediately after injury and for a varying number of days there is an increase of temperature in the peripheral parts supplied by the damaged nerve, yet in the course of about three weeks there is a decided fall of temperature, so that in by far the larger number of old nerve wounds the peripheral parts are cold and livid. The amount of loss of heat varies much. In one of Hutchinson's cases it was as much as 16° compared with the fingers of the opposite side, in two others 10°; and, indeed, it may vary between these and the normal temperature in a manner which admits of no rule being formulated. In a case brought before the Pathological Society,[6] the gradual restoration of heat, coinciding apparently with nerve repair, is well instanced. The patient was a boy aged six years and a half, who suffered division of his ulnar nerve in August 1861. In October of the same year the temperature of the fingers supplied by it was 10° lower than that of the others which derived their supply from the median and radial. On November 28th the difference was 5°. In July, 1862, the same. In February, 1866, there was only a difference of half a degree, and the muscles had resumed their normal bulk. Sometimes, however, even in cases of old injury, instead of any loss being discoverable, there is a distinct increase of heat, and Weir Mitchell found the temperature raised one or two degrees in cases of what he calls "causalgia." These cases seem comparable with those of increased sweating.

The *muscles* in connexion with a divided nerve undergo a rapid atrophy and degeneration, of a character which is completely different to the simple decrease in size which follows upon non-use. The final result of this process is a transformation of the muscle into a mass of fibrous tissue, firm and dense, neither contractile nor elastic, usually mingled with a little fat. For some time after the nerve lesion the muscle feels limp and flabby, the patient can exercise no control over it, and the tendon into which it is inserted no longer stands in relief under the skin; the muscle has, in fact, lost tone. This condition is gradually followed by wasting in bulk, and frequently by shortening of the muscle in its long axis. Vulpian describes a reduction in the diameter of the primitive muscle bundles, with granulo-fatty changes and complete disappearance of certain fibres: "In the early stage of alteration, the primitive fibres appear to be segmented, the muscular substance persisting in some places and being absent in others. At the same time we observe the formation of a more or less considerable quantity of fat-vesicles in the connective tissue which separates the secondary bundles of fibres, and much more rarely between the primitive fibres." Multiplication of the nuclei of the connective tissue of the muscle is also observed, while the vessels suffer only a loss of calibre, without other changes. The faradaic and galvanic excitability of the muscles is soon lost, but at present I shall not further allude to the changes in the electrical reactions, as I propose to treat of them at greater length in the section on Symptoms of Nerve Injuries.

(To be concluded.)

Address

Delivered on May 6th, 1887, at the Meeting held for the formation of an

ANATOMICAL SOCIETY.

By PROFESSOR HUMPHRY, F.R.S.

GENTLEMEN,—I fully appreciate the honour you have done me in voting me to the chair on this occasion. The reason for your doing so may be found in the fact that my commencement of the study of anatomy dates from more than half a century ago, during much of which time I have been a teacher of anatomy, and it is therefore pretty certain that I am the senior anatomical student as well as the senior anatomical teacher here present; and though I have now to a great extent relinquished the study and teaching of anatomy, yet it may be supposed that I still cast lingering looks behind upon that field in which I for so many years worked happily and earnestly, and, I hope, not altogether unprofitably. I appreciate the honour, however, more especially because I feel that this is an important occasion—an epoch, it may perhaps be regarded, in the history of anatomy, and an occasion of much importance to the study of medicine generally. We are met together for the purpose of elevating the study of human anatomy, and placing, or endeavouring to place, the science of human anatomy on a level with, and in that proper relation to, the other branches of natural science which I think it has not for some time held, and which relative decadence is greatly to be attributed to the fact that it has not advanced *pari passu* with them. Since the time of Hunter, Cruikshank, Astley Cooper, and the Bells, human anatomy has lacked its proper interest, and has not held its own with the other quickly progressing branches of natural science. Hence it has come to be regarded as a merely practical subject, and its study to be merely a process of piling fact upon fact without due regard to the purport of the facts and the suggestions to which they should give rise. Far be it from me to disparage the value of anatomy as a practical subject, seeing that in this way it confers the greatest benefits upon humanity, and has, and ever must have, the first and chief claim to our regard. Nor would I disparage the educational benefits resulting from the acquisition of a clear and accurate knowledge of the structure of the body and the mental training derived thereby, which is of so much value to those who are entering upon the pursuit of medicine. But I feel that the study of anatomy should not be regarded from this point alone, but that a wider and higher view should be taken of it. The human body is undoubtedly the highest and most perfect of created works, the last and most perfect outcome of nature's laboratory, the central one around which all the rest of the animal world is grouped, to which all point, and which all are calculated to elucidate. It is provided with a surpassing mechanism, great results being produced by slight modifications from the forms of other animals, and the resultant being such acuteness of perception, and such variety, nicety, and precision of movement, as to give man the mastery over all others, and enable him to bend all

Digitized by Google

nature to his purpose. Moreover, its proportions, the outlines of its form, and the power of expression of its several parts in both sexes and at all periods of life, are such, and present so much beauty and variety, that it has formed subjects for the highest efforts of the greatest artists of all times, from Phidias and Raphael to Leighton and Millais. Further, in it the physical is worked up into that complex and mysterious elaboration and process which enables it to become the organ or agent of the mental and intellectual, the seat of the soul, the abode of Deity. The problems and conceptions, physical, artistic, and psychical, arising out of and associated with this material frame of ours, infinitely surpass in number and interest those of all other existing forms. It may be regarded therefore as one of the marvels connected with it, that the study of it should come to be regarded as dull and uninteresting, and profitable only for its direct practical relations with medicine and surgery. Surely it needs only the proper impulses, such as we trust will in part be furnished by the proposed Society, to obtain for it a due appreciation and position among the higher and educational sciences. It was this feeling which urged me to contend strongly, and I am glad to say successfully, for a place for human anatomy among the natural sciences at Cambridge; and I am convinced that it would be a benefit vibrating along the whole line of medical education if at the early stage of that education the student were accustomed to reflect upon what he sees and reads of in his anatomical course, and to associate thoughts respecting the mechanical and other relations of the structures which he dissects. One of the greatest, perhaps the greatest, defect in medical education—I might say in all education more or less, but in medical education especially—is the heaping upon and oppressing the student's mind with a load of facts which he neither digests nor appropriates, and which he therefore does not retain. His mind is like a sack crammed with grain which there is little power to fertilise or utilise. Far better would it be to lessen the load and to substitute the habit and the ability to reflect and really digest and appropriate the remainder—to give some opportunity for mental elasticity, and for that enjoyment of study which results from a real knowledge and appreciation of what is learned. As a general rule, we remember only — at any rate, we remember best — that information the bearings of which we have well understood, and which has consequently most interested and impressed us, and which we have most enjoyed. To make anatomy better remembered and a better mental training, it must be made more interesting, more attractive, and more thought-inspiring; and this is to be done by giving to it its proper scope as a medium of information, and by imparting to its details, which are now too cold and dry and sterile, the warmth and life and thought-budding energy which should belong to them. I have spoken chiefly of human anatomy because to it these remarks especially apply, and because the human body is the subject of the most serious and arduous study, and the manner in which it is prosecuted is the most important and the most relevant to our purpose. Not that the scope of the proposed Society is to be limited to it, but that our greatest opportunities for good will be in relation to it. Anatomy—the anatomy more particularly of the human body—is a very ancient and dignified science; indeed, a royal science. It was studied ages and ages ago by the people on the banks of the Nile, from whom we have derived so much; and we were told the other day at Cambridge by my learned successor in the chair of Anatomy that the earliest writing upon it of which we have any cognisance was by an Egyptian king who had passed away long before the exodus took place. It is for us to make it a royal science in a higher sense, and to give to the human body its proper royalty of position in the animal world, not merely by having regard to the paramount practical importance of its study, but by considering it also in relation to its mechanism or physical physiology, in its relation to embryology, in its relation to the anatomy of other animals, and also in its relation to the special structural features which may be associated with the occurrence of certain diseases. The attendance this afternoon shows a general interest in this movement, and augurs well for the formation and prosperity of the Society, which, I trust, will prove long-lived and useful. I will occupy your time no longer, for the relation between the brevity of life and the length of art, and the value of brevity in word as well as in action, are becoming daily more manifest in the quickly shifting scenes of this singularly mobile age.

TWO CASES OF THOMSEN'S DISEASE.[1]

BY THOMAS BUZZARD, M.D.,

PHYSICIAN TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC.

So far as I am aware, no case of the remarkable condition to which the name of "Thomsen's disease" has been applied has yet been described as having been observed in this country. Examples have been reported from Germany, France, Russia, Italy, Sweden, and the United States, whilst the description given by Dr. Thomsen, of Kappeln, Schleswig, himself a sufferer and a member of a family largely affected with the disease, is well known as the source of the name which has been bestowed on the affection. I would refer those interested in the literature of the subject to a digest of it published by Dr. Paul Chapman in *Brain* (April, 1883), which has been continued up to date by Dr. Hale White in the same journal (April, 1886). These two articles contain an admirable summary of existing knowledge upon the subject.

The patient, E. C. F——, aged twenty, engaged in a commercial pursuit, was sent to me by Dr. Izod, of Esher, on account of a peculiar difficulty in the movements of his limbs. As long as he could remember he had always suffered more or less from this trouble, but it had been noticed especially of late when he began to enter upon the duties of his business. In his own words, "before doing anything he feels that he must get his muscles ready." If he has been at rest for a short time and goes to make a movement the muscles not only contract but remain contracted, so that a very strong effort on his part is required to make a fresh movement. He cannot run upstairs; after taking one step he is not ready to follow it up with another. On seating himself he is often unable to flex the knees, so that his legs remain for a time rigidly extended. And so, again, on wishing to rise the muscles appear to be "set," and it is only by strong exertion that he can effect the necessary movement. He has often fallen down upon a railway platform on alighting from a carriage, because he has been unready to take the second step necessary to preserve his equilibrium.

It is characteristic of his condition that the difficulty described is only temporary. After a few flexion and extension movements of the knee the tendency to stiffness ceases, and does not return until after he has rested for a few seconds. Thanks to this peculiarity, he can ride a tricycle very well after overcoming the stiffness which results from the first attempts to move the treadles; but if an impediment on the road should compel him to cease "paddling" he encounters the old difficulty in recommencing. So, likewise, he can play lawn tennis very fairly when he has overcome the stiffness which obstructs his movements at the beginning. In skating recently, he observed that if he were stopped suddenly, as in a collision, he could not go on again for a few seconds; and if he fell, he lay "like a log," unable at first to move a limb. He feels difficulty in beginning to run, but after a little while goes on very well. He can stop easily enough, but his limbs then grow stiff, and he cannot start again for a few seconds. The difficulty in beginning to move after rest, or in changing one movement for another, is intensified by anything producing "nervousness." If, for instance, he is called sharply, he finds his muscles more than ever unfit to obey the orders of his will.

The patient is a sturdy-looking young man of middle height, whose general health has always been excellent. When stripped the thighs are found to be extraordinarily developed, so that one is reminded, as he stands, of the sculpture of Michael Angelo, the muscles being sharply mapped out, and standing forth when in action in bold relief. When contracted they feel firm and hard, but in a quiescent state are perhaps inclined to be somewhat flabby. The actual muscular force, as tested by the power of resisting passive movements, is distinctly less than might be expected from the bulk of muscle displayed; and the patient himself says that he is not very strong, and somewhat easily tired. When seated and asked to extend the leg upon the thigh, it is only after an interval of several seconds that he can do so. And

[1] The substance of a communication made to the Neurological Society of London at the meeting held on Jan. 27th, 1887, when the elder of the two patients was exhibited.

Digitized by Google

in like manner, the leg being extended, he is unable until after a similar pause to place his foot upon the floor. The extensor cruris muscular mass is felt contracted, and relaxes only by slow degrees. During the relaxation the patient feels pain of cramp-like character in the muscle. Except for this there is not the slightest sensory disturbance—no cutaneous anæsthesia, numbness, or loss of muscular sense; and the muscles are not tender when handled. If he lies upon the floor, the difficulty experienced in rising to his feet reminds one to a certain extent of that shown by a patient suffering from Duchenne's myosclerosis (pseudo-hypertrophic muscular paralysis), and the hypertrophy of his muscles lends aid to this general resemblance; but, as will presently appear, the electrical reactions are completely opposed to those which characterise that disease. The act of rising is laborious, and the help of the arms is much called upon. The knee phenomenon is entirely absent in each limb, even when the Jendrassik method is employed for testing it. The cremaster reflex is present, but weak; the plantar so imperfectly elicited as to leave some doubt as to its presence. Although the tendency to a tetanoid condition upon voluntary movement is by far the most strongly expressed in the muscles of the lower extremities, it is not absolutely confined to these. The patient describes some unreadiness and stiffness in the use of his arms. His articulation is peculiar, recalling to a slight extent that of a patient with trismus; and the lower half of the face is a little suggestive of the sardonic expression to be noticed in a case of tetanus. Occasionally his eyelids will become partly fixed in a half-open position, so that for an instant he can neither open them further nor shut them.

Examination elicits no signs of increased excitability to mechanical stimulation in the anterior crural nerve. A galvanic current of one milliampère applied to this nerve produced no muscular contraction; with two milliampères there was evident contraction in the vastus internus and externus and KSZ < ASZ; but on a second trial with the same strength of current, the condition was reversed—KSZ > ASZ. The inference was that the excitability of the *nerve* to galvanism is not heightened.

As regards the *muscle*, a push with a finger-point upon the vastus internus causes a lumpy wave of contraction to rise, which lasts for many seconds after the finger has been removed. If this be repeated, however, several times in rapid succession, a normal condition is brought about, so that the contractions following percussion subside with ordinary quickness. If after this the muscle be left quiet for fifteen or twenty seconds and the finger then again thrust into it, the phenomenon described is reproduced. It is evident that, unlike that of the *nerve*, the mechanical excitability of the *muscle* is greatly heightened. The muscles respond to a normal strength of faradaic current, and there is contraction of the vastus internus to a galvanic current of two milliampères, and KSZ = ASZ.

In the extensor communis digitorum of the left forearm the interruption of a galvanic current from four milliampères is necessary to cause contraction, and KSZ > ASZ. The excitability to galvanism of the thigh muscle is therefore apparently considerably greater than that of the muscle of the forearm. The peculiar condition of the muscular system gives rise to a remarkable phenomenon. The contraction of the vastus internus muscle following electric stimulation can be seen to persist long after the rheophore has been removed, and on several occasions of examination an interval of twenty-five seconds was required for the gradual return of the muscle to a state of relaxation.

The above figure has been engraved from a photograph taken for me by Dr. Wilson, resident medical officer, National Hospital, Queen-square. It is intended to exhibit the contraction of the vastus internus remaining long enough after removal of the rheophore to be photographed.

A similar condition was noted in the sural muscles, and was also well seen in those of the thenar and hypothenar eminences of the hand. The muscles of the arm and forearm scarcely showed the peculiarity, and those of the face not at all. There was but little marked persisting contraction in the muscles of the front of the leg, which thus presented a considerable contrast to those of the calf, but it must be noted that the latter were considerably hypertrophied. When the rheophore—strong galvanic current—was drawn over the skin covering the vastus internus, the wave of contraction produced under it had not subsided ere another arose, and the appearance thus presented was very remarkable. This phenomenon, with the others described, has been noted by Erb and other observers.

The effect of mechanical and electrical stimulation upon the muscle is the same as that which accompanies volition, and it is to the persistence of induced contraction that the patient's embarrassment of movement is due. In strict correspondence, again, with what takes place as a result of repeated voluntary action, the exaggerated tonicity of the muscles passes off after a few repetitions of the application of electric currents, and then the contractions are observed to relax in normal fashion and in the usual time. After a rest of ten seconds only the phenomenon can be reproduced. The patient has no complaint to make as regards the action of the sphincters or of the muscles of respiration, except that he rather easily gets out of breath, but this he attributes to being out of practice in exercise. The heart sounds are quite normal.

E. C. F—— is one of a family of sixteen children, his father having married twice, and he being the second child of the second family, which numbered seven. The first child, a sister, has no trace of the affection, but a younger brother, W. F——, aged sixteen, is affected like himself. His muscles present the same remarkable development, and his symptoms generally are so precisely similar to those of the patient first described that it is unnecessary to enlarge upon them. But in two respects there is an important distinction. In the younger brother the vasti muscles show an increase of excitability to induced currents, and the knee phenomenon is preserved to a normal extent. No other children of either family (except these two) present, as I am informed, any trace of the disease. The father is described as being of somewhat anxious temperament, and so, it is thought, is the mother; but the size of their family must be remembered. The father has suffered from gout in the toe; the mother's father also suffered from gout, but died at the age of seventy-three. Nothing in the nature of this peculiar affection is remembered as regards any member of the mother's family.

It has been reported that persons affected with this disorder betray irritability of temper, suspiciousness, and reserve. This does not appear to be the case in the patients described. Indeed, the elder has been singularly liberal in affording opportunities for the observation of his symptoms, and has evinced a most intelligent interest in the requisite examinations; and the younger has cheerfully assented to investigation of his condition.

The symptoms presented by the two brothers are very characteristic of the disease, which has acquired its best known designation from the physician whose description of it in his own person and family first drew any particular attention to it. The term applied to it by Strümpell, "congenital myotonia," conveniently suggests the exalted muscular tonicity which is apparently the immediate cause of the symptoms; whilst "myotonic contractions," which has also been suggested, has the advantage of avoiding prejudice of the question whether the condition is always congenital, about which some doubt has been expressed. Allan M'Lane Hamilton of New York, in an interesting article (referred to by Dr. Hale White in his critical digest), is disposed to doubt whether the so-called Thomsen's disease is a distinct malady, and suggests that the muscle stiffness on contraction is a frequent symptom in a variety of maladies. But the microscopical examinations made by Erb and G. Fischer would appear to show distinct anatomical changes in the muscular fibres—hardness and want of suppleness in the muscular bundles, with marked thickening of the fibres and changes in their transverse striation, together with increase in the number of nuclei of the sarcolemma.

I have never seen in any case of disease of the spinal cord or peripheral nerves the peculiar condition observable in

Digitized by Google

these patients, who, it must be remembered, are, with the exception of the exalted muscular tonicity, in perfect health. There are no doubt remarkable tendencies to rigidity in certain organic and functional diseases of the nervous system, but they differ, according to my experience, from the state observed in Thomsen's disease, which is quite *sui generis*. In view of the fact that rapid repetitions of voluntary or mechanically induced muscle contractions will cause the abnormal tonicity of the muscle to disappear, at least for the time, it seems to me difficult to refer the peculiarity to the anatomical changes as a cause. One would perhaps feel more disposed to conjecture that these might be a result of a functional abnormality. But much extended observation will be required ere we can usefully discuss this point. I would refer incidentally to a circumstance of peculiar interest. In the view of some authorities the knee phenomenon depends upon locally induced contraction of a muscle, the tonicity of which it is essential should be well preserved. It would appear that the chief characteristic of the disease under discussion is an exaggerated tonicity of muscular fibres, and *cæteris paribus*, if the "tonus" theory of the knee phenomenon were correct, one would expect to find the response to a blow on the ligamentum patellæ more than usually well marked in such cases as I am describing. But instead of this the knee phenomenon is entirely absent in the elder of the two brothers. At the same time the cremasteric reflex is very weak, and the plantar only doubtfully present. In the younger patient, as I have remarked, the knee phenomenon is present. According to the summary derived by Dr. White from a consideration of the various recorded cases, it is the rule that the reflexes are normal. It does not seem that they are ever exaggerated.

It is scarcely necessary to remark that in the absence of any definite information as to the pathology of this affection nothing satisfactory can be said in reference to its treatment. As it is seen that exercise of the muscles, either by voluntary use or electric stimulation, conquers for a time the tendency to persistent contraction, trial is being made of the galvanic current, and regular exercise is recommended to the patients.

Grosvenor-street, W.

CASES OF TREPANATION OF THE MASTOID PROCESS.[1]

BY CHARLES WILLIAMS, F.R.C.S. EDIN.,
SURGEON TO THE NORFOLK AND NORWICH HOSPITAL.

CARIES and necrosis are more common in the mastoid than in any other part of the temporal bone. They are more frequently met with in childhood than in adult life, on account of the anatomical relations of the bone, which are highly favourable to the retention and consequent inspissation and putrefaction of the pus formed in suppurative inflammation of the mucous periosteal lining of the mastoid cells. If during the inflammation ulceration takes place, the bone, deprived of its periosteum, is very soon involved in the molecular necrosis of the tissues, and caries is the result. With caries of the mastoid process the posterior wall of the meatus is almost always deprived of its periosteum and perforated. This condition was well marked in two of the cases about to be related, as well as in a specimen removed from a boy who died of abscess of the brain. The specimen is interesting from the fact that the mastoid abscess perforated the bone in three places.

The first case is that of William K——, aged forty-nine, a coachman, who was admitted into the Norfolk and Norwich Hospital under my care in May, 1883, suffering from severe pains over the right side of his face and head; it generally commenced behind the ear and shot upwards, and was of a boring, grinding character; it made him feel very ill, and he looked as if he were in great suffering. Occasionally he had cold shivering fits, alternating with hot feverish attacks. He had a furred tongue and a temperature of 101°. He carried his head on one side, and drawn to the right shoulder. Behind the right ear the parts were red and œdematous; very tender when touched. Pus was being discharged from the meatus; it was seen to issue from a small opening behind the cartilaginous portions of the auditory canal on its posterior and upper side; a small granulation marked the spot. Hearing was most imperfect; the membrana tympani dull and convex. The man stated that his affection began four months before admission, after driving through a severe snowstorm, in which snow was driven into the right meatus. The same night he experienced pain in the ear. This increased in severity, and a month later the skin behind had become swollen, tender, and inflamed. This state of affairs gradually increased in intensity, besides extending down the neck, until the day of his admission. Ten days later he was placed under the influence of ether, and a straight incision made downwards over the mastoid process. As the tissues were infiltrated with inflammatory products, the incision was carried to a considerable depth before the bone was fully exposed, the condition of which was softer than usual. A small gouge soon penetrated it, and thick pus immediately oozed up. The opening was now carefully enlarged, and its connexion with the auditory tube followed up and also enlarged. The parts were well syringed out with carbolic water, a drainage-tube placed in the wound and drawn out through the meatus, and cotton-wool placed over all. A few days later an abscess, which had been forming deeply in the neck, opened into the wound and discharged very freely. A month after the operation the wound had healed, the membrana tympani was in a healthy state, and his hearing almost perfect. He was then sent to Yarmouth. In less than a fortnight he returned to the hospital suffering from an attack of erysipelas of the face and head, which rendered him delirious for a week. Eventually he got quite well, and I have seen him many times since. Even so lately as last week he expressed himself as being in excellent health, and his hearing good.

The second case was that of a young woman from whose right ear thin fetid pus was constantly discharging itself. There was a fistulous opening in the upper and posterior wall of the auditory canal, and another over the mastoid process. A probe could be made to pass from one to the other. She came under my care in this hospital with the hope of being relieved. She could give no account of the origin of her trouble. The membrana tympani was absent. Whilst under the influence of ether an incision was made over the mastoid, which was softer than it is naturally. All the carious bone was freely gouged away, and the opening extended into the auditory canal, through which a drainage-tube was placed. She recovered well, but had lost her hearing from disorganisation of the tympanum.

The third case was that of a schoolmaster in this city, who, when I first visited him, was suffering great pain and uneasiness over the left mastoid; it was severe enough to keep him in bed. No inflammation could be made out; no œdema over the mastoid. The membrana tympani was healthy, and hearing fairly perfect. For three months he tried every known remedy, both externally and internally, and failed to obtain the least relief; and, although there was no external sign of an abscess, I proposed as a last resource to cut down upon and open the mastoid process. The patient readily assented to this. The periosteum was found to be thickened, but not otherwise altered. This was freely incised, and I now attempted to perforate the mastoid with Hunter's trephine. So dense and hard was it that I utterly failed to make the smallest impression on it. Nor was I more fortunate with Marshall's necrotome. I was reluctantly obliged to close the wound from that day. My patient suffered no more pain; the wound healed rapidly, and at the present time—four years from the date of the operation—he is in perfect health, and free from any auditory annoyance.

Remarks.—Dr. Voltilini is the only authority who has directed attention to this peculiar affection, which he represented as a "form of mastoid periostitis undescribed by otological authorities." To him is due the credit of having given a clear and detailed description of this disease. "The ear," he observes, "may remain intact, but may sometimes in the course of the affection participate in the inflammation. The disease begins with severe tearing pains on one or both sides of the head, which extend to the side of the face and teeth." In three cases reported by Dr. Voltilini all were the result of cold and exposure. In one case, after the use of leeches, which did not diminish the symptoms, a long and deep incision was made over the mastoid. The pain was almost immediately relieved, the patient slept well, and made a good recovery. Dr. Turnbull[2] remarks:

[1] A paper read before the Norwich Medico-Chirurgical Society.

[2] Imperfect Hearing. Philadelphia, 1881.

Digitized by Google

"A study of these cases (one by Dr. Blake of Boston, one by Dr. H. Knapp of New York, and my own) shows the disease to be neither one of the auricle, the external auditory canal, the tympanic cavity, nor the mastoid cells, but one that originates without, and not within, the ear, and one that might progress inwards, but would hardly penetrate deeply.

The next case was that of a boy aged seven years, under my care in the Norwich Hospital, and very kindly transferred to me by Mr. Cadge in December, 1885. He had an attack of scarlet fever five years ago, and from that time has suffered from otorrhœa of the left ear. Three weeks before admission he complained of severe pain in the head, especially about the vertex; he had a peculiar way of looking upwards, and generally carried his head on one side (the right); he used to walk against things as if he had lost his sight, and had occasional attacks of vomiting. He is fairly well nourished, of light complexion; has a vacant expression; was able to read and write, but can do neither now, the sight being so imperfect, so much so that he cannot distinguish letters. The pupils are widely dilated and act feebly. In walking he proceeds very cautiously and slowly. Is dull and stupid. Has no paralysis, either facial or lateral. There is a free offensive discharge from the left ear, and a tender swelling behind. The membrana tympani and ossicles absent. On Jan. 8th, 1886, he was etherised, and a long deep incision made over the mastoid process. A good deal of pus was found to be lying under the periosteum. The surface of the bone was rough and carious. This was chiseled away, the mastoid cells freely opened, and a communication made into the auditory canal. A drainage-tube was passed into the wound and out through the meatus. The wound was well syringed with boracic lotion, and the ear covered over with carbolised dressing. Two months later the wound had healed, the discharge had ceased, the boy was less dull, could see well, and run about without fear.

Remarks.—Of all cases within the domain of surgery no case is so likely to terminate fatally if left to itself as that of inflammation of the tympanum, whether it be acute or chronic; and no case is so likely to end well as such a one if operative proceedings are adopted early. An abscess in the immediate vicinity of the brain carries with it grave danger, and the early opening of that abscess is the only protection against the destructive effect of pent-up matter. Surgeons, as a rule, hesitate too long in dealing with abscess of the mastoid process; precious time is thus lost, irreparable mischief is sustained by the structures of the tympanum, and a fatal termination from abscess of the brain, meningitis, or pyæmia is too frequently the result. On this point Hinton observes: "I have never regretted making the incision, and scarcely ever decided against making it without regretting that I did not." Sir William Dalby says: "No time should ever be lost in providing an escape for pus. Pain and tenderness over the mastoid process should always demand immediate attention, and especially when the tympanic membrane is perforated. If, in addition, there should be any redness or pitting upon pressure, it may be assumed with great confidence that there is pus in the mastoid cells." At the same time, a word of caution on one or two points in connexion with this operation may be useful. It is well to remember how near the lateral sinus is; it lies immediately behind the mastoid process; and if this process has become softened from the long retention of pus within its cells, a condition results named by some "caseous degeneration." The trephine or chisel may readily slip through this into the sinus. As a precautionary measure the finger-nail or the point of the scalpel should be pressed against the bone; and if it does not yield we must proceed to operate with the gouge or trephine. The form of trephine I like best is that used in America, and known as Dr. Buck's. It is a more manageable instrument than Hinton's, and more under control. I have had fitted to mine a small conical-shaped necrotome, which will be found of great use. Having perforated the bone with the trephine, the necrotome can be used to enlarge the opening; but should the bone be soft, Volkmann's scoop is unquestionably the safest and best instrument with which to scoop away all carious bone.

AT the annual meeting in connexion with the Association of Public Sanitary Inspectors, on the 7th inst., the President (Mr. Edwin Chadwick, C.B.) delivered an address on the Financial Value of Sanitary Science.

PARALYSIS OF THE DIAPHRAGM AFTER DIPHTHERIA, WITH EXTENSIVE PULMONARY COLLAPSE; RECOVERY.

BY W. PASTEUR, M.D. LOND., M.R.C.P.,
PHYSICIAN TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN, ETC.

J. H——, five years of age, came to the out-patient department of the North-Eastern Hospital on May 3rd, 1886, with the following history. During convalescence from chicken-pox in March his mother noticed a swelling (probably glandular) on the right side of his neck, but the child did not complain of pain or difficulty in swallowing, and there was no regurgitation of liquids through the nose. On April 26th the boy was in perfect health, but shortly after this he began to languish and became rapidly weaker. It was also noticed at this time that he began to walk in a very peculiar manner. He reeled into the out-patient room like a drunkard; his gait was markedly ataxic and unsteady. No obvious paralysis of the soft palate could be made out, but the voice had a nasal "timbre." The heart was acting strongly, the pulse being full and regular. The knee-jerk was absent on both sides.

The child was taken into the hospital a week later in the following condition. A fairly nourished, somewhat frail-looking boy, with a dry, cool skin, healthy lungs, and good pulse. Nervous system. The intelligence is good, the expression rather listless. There is no facial paralysis. The pupils are equal and active, and the ocular muscles healthy. The tongue is protruded in the median line. The child swallows slowly, but there is no regurgitation of food. The voice is weak and nasal in quality. The movements of the soft palate are very limited, but equal on the two sides. There is marked paresis of the muscles of the trunk and extremities. The child is unable to sit up in bed without assistance; the grasp of both hands is very feeble, and when put upon his feet he begins to sway to and fro, and would fall if not supported. Tactile sensibility, as far as can be ascertained, is intact. The knee jerk is absent on both sides, but the superficial reflexes are all readily elicited, and with one exception (the plantar) remained present throughout the illness. There is no ankle clonus. Since the beginning of this illness the patient has been troubled with rather obstinate constipation. There is incontinence of urine, which, however, existed previously. The child has a slight dry cough, but examination of the lungs does not reveal any abnormal physical signs.

Progress and termination.—The first sign of heart failure appeared on May 13th, when the pulse became irregular and increased in frequency. On the following day paralysis of both legs was absolute. The plantar reflex was a little delayed, and tactile sensibility in the legs appeared to be blunted. The patient was still able to take his food and stimulants by the mouth, though with some difficulty, and an odour of sour milk was perceptible in the breath. During the next few days there was a gradual increase of the paralysis of the trunk and arms. The movements of the ribs seemed to grow less day by day; the head rolled helplessly to one side or other when unsupported; the child had lost all power of movement over both shoulder-joints, but was still able to move the forearms and hands, though even here muscular power was almost in abeyance. The voice meantime had sunk to a whisper, and the cough was aphonic and ineffectual, having almost entirely lost its explosive character. Up to this time the treatment had been of the simplest. The child was placed in a curtained cot in a warm corner of the ward, and strict orders were given that he should be moved as little and as gently as possible. Constipation was relieved by simple enemas as often as necessary, and small doses of liquor strychniæ were administered every four hours. The diet consisted entirely of milk and beef-tea, with an ounce and a half of brandy in the twenty-four hours. At this period of the illness the most serious factor was the great difficulty experienced in getting the child to take a sufficient quantity of nourishment. Owing to the very slow and imperfect manner in which the act of swallowing was performed, it was found impossible to give more than two or three teaspoonfuls of food at a time, and this made the total quantity for the twenty-four hours far below what one would have wished the patient to take. During the last forty-eight hours, too, the ingurgitation of food had given

Digitized by Google

rise to one or two severe paroxysms of coughing, which greatly exhausted the child. It was accordingly decided to make up the deficiency by giving nutrient enemata. On the following morning (May 20th) an alarming train of symptoms suddenly developed. Respiration became greatly embarrassed and the lips and extremities cold and bluish. Examination of the chest showed that the right side was practically immobile, with the exception of the two or three upper ribs. The percussion note was much impaired over the right front and right base. At the right apex in front the breathing was loud and tubular in the upper spaces, weak over the middle lobe, and almost inaudible at the base. Behind, above the level of the scapular angle, the breath sounds were fairly loud and bronchial. No crepitations or râles could be discovered. (Morning temperature 99·4°; evening 99°.) The quantity of stimulants was increased to three ounces per diem.

On May 21st the child was much weaker. The front of the chest was alone examined. There was weak tubular breathing without râles and impaired resonance all over the right front, with exaggerated breath sounds on the left side. The heart was not displaced; its action was rapid and feeble (144). The movement of the right half of the chest in respiration was just appreciable, and it was observed that the epigastrium receded during each inspiration, whilst it bulged very slightly during expiration and more distinctly so during cough, an indication of partial if not of complete paralysis of the diaphragm. The cough was ineffectual, very frequent, and much aggravated by giving food, owing no doubt to a certain amount of leakage into the air passages. The temperature was rising (100°), and the pulse (144) becoming thready. The condition of the child was critical; indeed, there seemed but little hope of recovery. The chest was wrapped in cotton-wool, and food by the mouth entirely withheld, nutrient enemas of pancreatised milk or beef-tea with brandy, three ounces every four hours, being substituted. Further, the house-surgeon was directed to give hypodermics of brandy and ether (half a drachm of each) at intervals of a few hours, if necessary. Some half-dozen injections were given in the course of the following two or three days. The next day there was no improvement in the patient's condition. The temperature was 102°, and the pulse, in spite of free stimulation (brandy, four ounces), was weaker and more thready (156), and only just perceptible at the wrist. On May 23rd the temperature reached 102·4°, and the case appeared quite hopeless. During the night, however, the severity of the symptoms abated somewhat, and there was a very slight but appreciable improvement on the morning of the 24th. The return of movement in the right side of the chest and a rapid disappearance of the signs of diaphragmatic paralysis were amongst the most favourable signs. Examination of the backs (first time) revealed the existence of bronchial and tubular breathing at the right apex and posterior apex of the lower lobe. At the extreme base there was distant weak breathing, probably due to collapse. Over the left back there was exaggerated breathing. The child now continued to improve slowly. Swallowing soon became easier, so that on the 26th he was able to take seventeen ounces of liquids by the mouth. (Nutrient enemas reduced to three in the twenty-four hours.) On the 28th every sign of diaphragmatic paralysis had disappeared, and the two sides of the chest moved almost equally. The physical signs at the right apex continued much the same (dulness, tubular breathing, bronchophony, &c.). There were a few coarse crepitations of doubtful nature in the right axilla, which rapidly disappeared. The cough was still troublesome, but had to some extent regained its explosive character. The pulse rate had fallen to 108; the pulse was of fair strength and regular. Temperature normal. On May 31st the patient had regained some power over the shoulder-joints, and there was evidence of a general, if slight, recovery of muscular power. The knee jerk was still completely in abeyance. Swallowing had so far improved that the nutrient enemata were discontinued. A few days later the last sign of imperfect deglutition—the sour milk odour of the breath—had disappeared. There was now harsh breathing, without râles, at the right apex, with a little dulness at the angle of the scapula and weak breathing at the base. On June 11th the child was allowed to sit up in bed for the first time. The voice had returned, but was still "reedy." The movements of the soft palate were normal. (Takes food and stimulants well.) There was considerable power in both legs, with marked incoördination of movements. The plantar reflex was not obtained on either side; the other superficial reflexes were normal. Physical signs in chest quite healthy. Heart strong and regular. From this date convalescence was uninterrupted. The plantar reflex returned towards the end of June. In the first week of July the child began to walk with assistance. For some time his gait was very ataxic as well as feeble. He was discharged cured on July 24th, but the return of the knee jerk was delayed for several weeks longer.

Remarks.—The features of this case which call for comment are (1) the paralysis of the diaphragm; (2) the nature of the lung affection, and its relation to the diaphragmatic palsy. Paralysis of the diaphragm after diphtheria is of sufficient rarity to deserve mention, and, as far as I can ascertain, recovery from this complication is very rare indeed. Under any circumstances paralysis of this muscle is attended with very grave danger, and when it is borne in mind that in the present instance it occurred in a child with all four limbs paralysed, with great enfeeblement of the muscles of the neck and trunk, and with unmistakable evidence of severe heart disturbance, the recovery of the patient furnishes a striking example of the extraordinary recuperative power possessed by children, and of the paramount importance of leaving nothing undone in the way of treatment on the plea that a case is hopeless. The extreme feebleness of the respiratory movements rendered the signs of the paralysis less obvious than usual. But the superior costal type of the breathing, the complete loss of inspiratory protrusion at the epigastrium, with protrusion during, but not before, attempts to cough, were sufficiently marked to make the diagnosis a matter of certainty. And if confirmation had been needed, it was furnished by the rapid return of normal physical signs and respiratory movements, coincident with the disappearance of the clinical signs of diaphragmatic paralysis.

Of the exact nature of the lung condition it is not easy to speak with certainty, but it is important to note in this connexion that for two or three days previously there had been evidence of slight leakage of fluids into the air passages, and that the cough was powerless to clear the bronchi of any obnoxious material—a condition of things favourable to the production of collapse or bronchial irritation. It is just possible too that some temporary arrest or disturbance of function in the right vagus nerve was a factor in the causation of the changes observed. The physical signs were those of collapse of the base (there was no pleural effusion), with pneumonia or broncho-pneumonia and collapse of the remainder of the lung. The onset was unlike that of croupous pneumonia. There was no rigor; the temperature rose gradually, reaching the highest point (102·4°) on the fourth day, with a morning remission each day. The respirations increased from 24 to 48, and the pulse rose to 144. There was a rapid fall of temperature and amelioration of symptoms on the fourth day, which coincided with the return of diaphragmatic movements. The speedy disappearance of the abnormal physical signs at the apex and the almost complete absence of crepitation or râles from first to last in every part of the affected lung would seem to show that simple collapse preponderated largely over the pneumonic element—if, indeed, this was ever present to an appreciable extent. The limitation of the lung condition to one side admits of two explanations: either the right half of the diaphragm was more paralysed than the left, of which there was no other evidence; or, which is more probable, there was a temporary paresis of the right intercostal muscles, especially in the lower interspaces. In conclusion, I would draw attention to the powerful stimulating action of the hypodermic injections of brandy and ether, without which I doubt whether the child's life would have been saved.

Queen-street, Mayfair, W.

VICTORIA HOSPITAL FOR CHILDREN.—A festival in commemoration of the twentieth anniversary of this charity was held on the 6th inst., the Duke of Cambridge presiding. The main object of the festival was to provide funds for a large addition to the hospital buildings which were opened by the Prince and Princess of Wales in June, 1886. Last year the number of in-patients was 561, and of out-patients 37,566; the aggregate number attended to since the foundation of the charity being 364,164. During the evening subscriptions and donations amounting to over £1200 were announced by the Secretary.

CANCER AND PHTHISIS AS CORRELATED DISEASES.

BY W. ROGER WILLIAMS, F.R.C.S.,
SURGEON TO THE WESTERN GENERAL DISPENSARY; SURGICAL REGISTRAR TO THE MIDDLESEX HOSPITAL.

IN consequence of the unity of nutrition existing among all the parts of every living thing possessed of any organic solidarity, changes of nutrition affecting an individual part necessarily react on other parts. This relation, which is known as correlation, was first clearly pointed out by Cuvier with regard to normal states, and it is equally applicable to morbid conditions. Such correlations are, indeed, very numerous. They may be regarded as the outcome of a powerful synthetic tendency, which causes the individual whole to be as much conditioned by its parts as each part is conditioned by others. But why changes in this or that part should be linked with this or that particular correlation, whilst variations in other parts, apparently equally important, excite no such correlated changes, is for the most part beyond our ken. In some instances the developmental history of the correlated parts gives us a clue, as in the case of homologous structures, such as teeth and hair, which are particularly liable to vary together. But very often no such indication can be discovered. We cannot say whether one part governs the others, or whether all are governed by some earlier synthetic tendency. Why, for instance, should colour and constitutional peculiarities go together? What connexion is there between deficiency in pigment and such changes in the muscular and osseous systems and in the general constitutional condition as albinoes exhibit? Why should such individuals be weaker in body, more delicate, and more feebly developed than others with pigment of their own species? Why, too, should the degree of development of pigment in the epidermis so greatly influence the susceptibility to certain diseases and drugs? How is it that red-haired persons are more liable than others to melanosis? Why are white cats with blue eyes nearly always deaf, and why are white horses distinguished from their coloured congeners by special liability to sarcomatous tumours? A similar question might be asked with regard to the curious correlations seen between quite distinct parts in many cases of monstrosity. In all of these instances no explanation is possible in the present state of our knowledge. Indeed, the subject has been but little investigated. In this wide uncultivated field rich harvests may be gathered.

I now propose to point out, in the briefest manner possible, the correlation between cancer and phthisis. For detailed treatment of the subject I must refer the reader to the Middlesex Hospital Surgical Report for 1885. The following facts show that there is the most intimate connexion between the two diseases. The widespread belief as to the incompatibility of phthisis and cancer is attributable to the erroneous teaching of Rokitansky. That such a grossly inaccurate statement should ever have obtained credence shows the folly of blind submission to authority in such matters. The chief evidence to be cited may be arranged under two heads:—

1. As to *family history*.—(*a*) Of 134 families subject to *breast* cancer, one or more relatives, among the adults, were known to have died of, or were subject to, phthisis in 74, or 55·2 per cent. (*b*) Of 129 families subject to *uterine* cancer, one or more relatives, among the adults, were known to have died of, or were subject to, phthisis in 60, or 46·5 per cent. (*c*) Similarly, of 53 families subject to cancer of the *tongue* and *mouth*, phthisis prevailed, among the adults, in 17, or 32 per cent. Thus in these 316 cancerous families there was a history of phthisis in 151, or 47·7 per cent. There was a history of both phthisis and cancer in the same family in 18 cases out of 134 families subject to *breast* cancer, and in 14 cases out of 129 families subject to *uterine* cancer. In a large proportion of the foregoing cases the causes of death were unknown. If these had been eliminated, the amount of phthisis would have appeared much greater, as may be judged from the following statements in which this has been done. Thus, 40·9 per cent. of the fathers of patients with *breast* cancer were of phthisical families, and 33·9 per cent. of the mothers. Of the fathers of patients with *uterine* cancer, 40 per cent. were of phthisical families; and of the mothers, 30·3 per cent. Of the fathers of patients with cancer of the *tongue* and *mouth*, 29·4 per cent. were of phthisical families; and of the mothers, 5·8 per cent. With regard to the prevalence of phthisis among these patients' *brothers* and *sisters*, in 88 families subject to *breast* cancer there were one or more deaths from phthisis, among the adults, in 40; in 81 families subject to *uterine* cancer, in 41; and in 52 families subject to cancer of the *tongue* and *mouth*, in 14.

2. As to the *necropsies*.—(*a*) Of 44 necropsies for breast cancer, old arrested phthisical lesions were found in 4 instances; and in 2 other cases the patients had died with phthisis in active progress. (*b*) Of 88 necropsies for uterine cancer, old arrested phthisical lesions were found in 12 instances. (*c*) Of 34 necropsies for cancer of the tongue and mouth, in 5 cases old arrested phthisical lesions were found; and 4 other cases had died with phthisis in active progress. Thus in these 166 necropsies cancer and phthisis were found associated in 27 cases, or 16·2 per cent.

PNEUMONIA.

BY REGINALD G. ALEXANDER, M.A., M.D.,
CONSULTING PHYSICIAN TO THE BRADFORD INFIRMARY, AND PHYSICIAN TO THE HALIFAX INFIRMARY.

THE subject of pneumonia, at all times interesting, has been specially brought before my notice during the last week, having seen a number of cases, brief notes of three of which, occurring under different forms, by way of illustration I extract from my note-book. By the perfection of our modern diagnosis the physical signs of pneumonia are perhaps more defined and certain than in any other disease. Conditions of weather and climate are no doubt chief factors in its production, especially a climate which is variable and damp; but all debilitating conditions of the system specially predispose to the disease. The symptoms are too well known to require enumeration. The prognosis is grave in proportion to the implication of both lungs, the number of respirations, temperature, state of pulse, and nervous system. In protracted cases the possibility of indurative consolidation must not be overlooked, as in Case 2. In considering treatment, we must recognise the fact that it is a general and not a local affection with which we have to deal. The heroic methods of the past, which caused great mortality—venesection, large doses of tartar emetic, &c.—had for its aim the cutting short of a local affection. The great danger in pneumonia is cardiac failure, and it is necessary to husband the strength until the disease subsides. If hyperpyrexia is the prominent symptom, the treatment by baths adopted abroad is certainly justifiable, with the object of diminishing the injury to the heart by the pyrexia, and it is occasionally useful when, with a high temperature, great dyspnœa threatens life. There is always a danger of falling into routine treatment. Every case should be treated on its own merits, as the disease requires different management under different conditions. Pneumonia neither requires nor will it endure the active measures which were formerly practised. We should have clearly before us what we intend to acomplish by any particular line of treatment, and in this way, and in no other, will our success in the great majority of cases be complete and satisfactory.

CASE 1.—I saw with Dr. Windle at Ovenden on Sunday night, Feb. 13th, a young man, previously healthy, suffering from acute croupous pneumonia. His dyspnœa caused him to concentrate all his efforts on breath-getting. Respiration 72; pulse 130; temperature 104°. Sputa bright-red blood; absolute dulness of left lung, anteriorly and posteriorly; bronchial breathing and bronchophony well marked. Diagnosis: Pure pneumonia, second stage. Prognosis hopeful.

CASE 2.—On Feb. 12th, and again on the 14th, I saw at Southport a case, with Mr. Heath, of very different character. A young lady at school, aged eleven, had been under Mr. Heath's care suffering from catarrhal pneumonia of the left lung for three weeks. All had gone well, the only unusual symptom being a temperature lower at night than in the morning (evening temperature 101°; morning 102·5°). The lung had cleared up, with the exception of the lower third of the base posteriorly, which was consolidated, and at the line of healthy and solidified lung marked bronchial breathing and bronchophony existed. Tongue furred. Pulse 108, somewhat sharp; respiration only 18. Lung expansion elsewhere very good. The diagnosis was uncertain

Digitized by Google

on account of the family history: chronic interstitial pneumonia or tubercular deposit.—May 8th: The patient has steadily improved, is still under Mr. Heath's care at Southport, and able to walk and drive out daily.

CASE 3.—On Feb. 9th and subsequent days I attended a lady aged thirty-seven, married, with children, who for ten months had suffered in consequence of domestic bereavements from complete anorexia, want of sleep, dyspnœa, and general debility. The day previously to the attack she had exposed herself to inclement weather, and developed acute croupous pneumonia of both lungs. There was also mitral insufficiency and excited loud bruit, with great cardiac impulse. Respiration 76; pulse 150; temperature 105°, intermittent and flickering; clammy sweat. She was apparently sinking. She was ordered mustard and linseed poultices, eggs and brandy, alternating with port wine and stimulants generally; drachm doses of steel wine and dilute hydrobromic acid, with compound conium and morphia pill (¼ gr.). The patient would have died during the night but for the unsparing use of stimulants, which were continued for several hours until the pneumonic symptoms had subsided. On the 16th her condition had greatly improved, sleeping and eating well.

In simple cases of pneumonia, however, no stimulants may be required, and an expectant plan of treatment which does not interfere with nature's efforts at a cure is the plan most desirable and efficacious.

Halifax.

ON A CASE OF PERSISTENT PRIAPISM.

BY J. MACKENZIE BOOTH, M.A., M.D.,
PHYSICIAN TO THE ABERDEEN GENERAL DISPENSARY.

CASES of persistent priapism crop up in practice from time to time, but their occurrence is rare enough and their causation sufficiently obscure to merit a passing notice. Several cases of this nature lasting from one to four months are recorded in THE LANCET in 1845, 1867, and 1873, in most of which excessive coitus was the exciting cause. In a case lasting for six weeks, which recently came under my observation, no such cause was present, nor was there any coexisting injury or disease of the spinal cord or nerve centres to account for the condition.

The patient, W. S——, a seaman, aged fifty-five years, was a married man with twelve children, most of whom were grown up. Save for a dysenteric attack thirty years before, which prostrated him for six weeks, he had always enjoyed good health. He had always been of temperate habits, and had never suffered from venereal disease. While at sea on June 27th last, he awoke in the morning with the penis erect and very painful, especially at the root. He said that the day before he had been exposed to cold and wet. Two days later, during which he was unable to sleep for the pain, he came under my care. I found him lying in bed with his knees drawn up so as to prevent the bedclothes from touching the affected parts. The penis was erect, hard, painful to touch, and bent backwards along the abdomen in the middle line, and the scrotum was much relaxed. The pain was most severely felt on either side of the crus, and the parts there were found to be hard, swollen, and exceedingly painful to touch. Otherwise he was quite well and had been in robust health up to the time of this seizure. There was no other disease of the urinary apparatus or rectum discoverable, and the urine was normal and easily passed. A purgative was administered, and half-drachm doses of the bromide of potash ordered to be taken twice daily. This was continued steadily for four days without the slightest change in the affected organ. On the second night an enema of a drachm of laudanum in two drachms of starch was given, after which the patient had a few hours' sleep. On the fourth day ice was applied to the penis and continued for over a week. Small doses of tartar emetic combined with morphia were also administered at intervals, nausea being occasionally induced. Still, the penis remained as turgid as ever, and exceedingly painful to touch. During the next four weeks, after consultation with the late Professor Dyce Davidson, everything that we could suggest to relieve the painful condition was tried. Oleate of morphia and other anodynes rubbed into the penis and perineum, and morphia suppositories, gave only temporary relief to the pain. Blisters were applied over the perineum, and free leeching both over the perineum and the penis itself, were resorted to, but without appreciable effect. The amount of turgescence varied slightly from time to time, but was not materially reduced at the end of the fifth week. During all this time, too, the hardness, swelling, and pain were most marked over the muscles at the root of the penis, and there was total absence of sexual desire throughout. In the beginning of the sixth week he was ordered five-grain doses of the iodide of potash in mixture, to be taken four times daily. From that time there was a steady improvement, till in a fortnight's time—i.e., at the end of the seventh week—the penis had wellnigh regained its wonted condition, and the patient was able to don his nether garments and walk about without pain. He shortly afterwards resumed his seafaring life, and since then he has had no recurrence of his troublesome malady.

In the above case the causation was different from that of most of those previously recorded. In these the history of injury of nerve centres or excessive coitus generally pointed to distant or reflex nervous irritation as the main cause of the priapism, but here it was evidently due to local inflammation about the muscles constricting the bulb of the penis. The marked swelling, hardness, and pain over these muscles, coming on a few hours after exposure to cold and wet, and continuing while the turgescence of the penis lasted, indicated continued obstruction to the venous efflux as the chief factor in its causation. The exhibition of the iodide of potassium seemed to have a beneficial effect in hastening the recovery, as up to the date of its administration the symptoms had shown no sign of abatement, while immediately thereafter gradual improvement took place, terminating in complete relief in fourteen days. The perusal of a closely analogous case reported by Dr. Mitchell Bruce in THE LANCET (vol. i. 1873, p. 90) led to its adoption. In that case also the patient was a man of fifty-five years, the priapism lasted six weeks, and it subsided in twelve days during the exhibition of the iodide of potassium.

WESTMINSTER HOSPITAL.

PUNCTURED WOUND OF BRACHIAL ARTERY; ARREST OF HÆMORRHAGE BY PRESSURE; SECONDARY BLEEDING ON TWENTIETH DAY, WITH FORMATION OF DIFFUSE ANEURYSM; LIGATURE OF VESSEL; REMARKS.

(Under the care of Mr. A. MARMADUKE SHRILD.)

WOUNDS in the neighbourhood of the larger arteries are always of importance, and cause much anxiety to the surgeon until the danger of secondary hæmorrhage is over and the wound healed. It is often difficult to say from the character of the hæmorrhage and the colour of the blood whether the loss is from artery or vein, and if free pulsation is felt in the artery below the region of the wound the difficulty is increased. The following is a case in which the more serious symptoms in connexion with the artery were developed twenty days after the wound, probably from the sudden giving way of the cicatrix in the vessel wall, due to the severe strain received in falling.

A stout muscular man of intemperate habits, aged twenty-seven, was stabbed on the front aspect of the right arm, near its lower third, by a penknife. He also sustained a deep cut above the nose. These injuries were inflicted during a drunken brawl on Dec. 14th, 1886.

On admission there was free bleeding of an arterial nature from the wound, but the pulse at the wrist was not altered in force and volume. The hæmorrhage was readily arrested by bandage and compress. The man was intolerant of treatment or confinement, and left the hospital on Dec. 18th at his own request. There had been no marked return of

Digitized by Google

the bleeding. He attended irregularly as an out-patient, the wounds on the head and arm healed, and the hæmorrhage seemed to be permanently arrested. On Jan. 2nd the patient resumed his avocation of grinding knives and scissors, but his arm became so swollen and painful that he had to desist. The next day, twenty days since the infliction of the wound, he fell down while skating. Profuse bleeding occurred from the wound again, and he was brought in haste to the hospital and admitted under the care of Mr. Cowell, who kindly transferred the case to Mr. Sheild for treatment. The patient, who had been leading during Christmas-time a life of continuous debauchery, was ill and feverish. His tongue was coated and tremulous, his limbs shaky, and he appeared to be on the verge of delirium tremens. The right arm was enormously swollen, hard, tense, and somewhat discoloured. No pulsation or bruit could be detected over the swollen parts. The hand was œdematous and cold, the radial pulse completely absent. The patient complained of terrible pain in the limb, and said the hand felt "numbified." On removing the temporary compress, a jet of blood the size of a small quill issued in a continuous flow from the punctured wound. This blood was venous in colour, and pressure on the artery above lessened but did not check its discharge. The patient being anæsthetised and Esmarch's apparatus lightly applied, the opening was enlarged, and the finger passed into a large irregular cavity, full of soft, warm clot. This was freely laid open by an incision some four inches in length along the inner side of the biceps muscle, and a quantity of clot sponged away. The parts were so disintegrated that the source of the bleeding or the position of the main vessel could not be accurately determined. A bent probe was employed as a searcher, and this device was soon successful, the end of the instrument passing into an opening in what was evidently the brachial artery. The aperture was transverse and clean cut, and would have admitted the end of a No. 8 catheter. It was situated at the upper part of the middle third of the vessel. The median nerve was clearly seen, and held away, while the artery was tied with carbolised silk above and below the wounded part. The large cavity was then dusted with iodoform, and lightly packed with gauze, being left quite open. The whole limb was wrapped in wool and bandaged evenly.

The after progress of the case was satisfactory, and can be briefly related. A large amount of sero-sanguineous discharge poured from the wound. The limb rapidly diminished in size, and the constitutional symptoms of fever and pain soon subsided. The day after the operation the patient repeatedly expressed his relief from its performance. On the third day after the operation, when the wound was being dressed, smart bleeding occurred. The source of this was a small arterial twig obviously enlarged by the collateral circulation. A ligature was easily applied in the open wound, and no further bleeding occurred. The hand felt numb and powerless for several days, but the circulation was active, and a radial pulse was established on the tenth day. The ligatures separated on the sixth and fourteenth days. The wound was practically healed on the thirtieth day after operation, being gradually brought together by bandaging. The incision, which seemed so extensive in the swollen condition of the parts, was not more than two inches and a half long when the arm had resumed its normal dimensions.

Remarks.—The first point of interest in this case is the fact that the radial pulse remained unaffected, though the brachial artery was badly cut. Most surgeons are familiar with similar instances. Provided that an artery be not completely divided, a small portion of it seems sufficient to guide the blood into the distal part of the injured vessel. The sequence of events observed here not uncommonly occurs in wounds of the main vessels treated by pressure. The orifice in the vessel is temporarily sealed by clot and the pressure of surrounding tissues; some accidental movement displaces these frail barriers, and fresh bleeding takes place externally or into the tissues of the limb. The latter variety is much to be feared, for, in addition to the loss of blood, the patient has to combat the danger of gangrene caused by the pressure of the extravasation, and the surgeon may be misled by the absence of external bleeding. This variety of hæmorrhage reminds one of the concealed or "occult" bleeding spoken of by obstetricians. Still, the fact must not be lost sight of that a considerable number of cases of punctured wounds of the main vessels can be perfectly treated by pressure. But the surgeon who undertakes this must be careful that the pressure is applied properly, and he must be assisted by quietude and tolerance on the part of the patient. The colour of the blood when the hæmorrhage recurred was venous rather than arterial. The plan of searching for the orifice into the artery, after laying open an aneurysm or hæmorrhagic cavity by a probe or catheter, was very successful in the present instance. The great use of Esmarch's apparatus and the importance of making a very free incision in these cases are well exemplified. The course adopted in leaving this deep wound quite open was justified by the free drainage of serum which took place from its extensive cavity. Had the margins of the wound been united, retention of inflammatory products and tension, with its attendant evils, must have resulted. It is an important consideration that in punctured wounds of a limb the main vessels may be injured, and yet the wound caused by the entrance of the instrument be far removed from the known course of the vessels. Thus a stab on the front of the lower third of the thigh may wound the femoral artery near the adductor opening. In the present case the knife had passed obliquely from without upwards and inwards through the biceps muscle, and its point had notched the brachial artery in its middle third.

NORTH-WEST LONDON HOSPITAL.

STRICTURE OF THE URETHRA PRESENTING UNUSUAL DIFFICULTIES; REMARKS.

(Under the care of Mr. MAYO COLLIER.)

FOR the notes of this case we are indebted to Mr. Cecil Christopherson.

Edward S——, aged thirty-one, railway porter, was admitted on the morning of September 5th suffering from retention of urine. He had come from Leeds the day previously, and since then a few drops of urine only had passed. Four years ago he had a similar attack, and was admitted into the Leeds Infirmary, under Mr. Jessop, who with great difficulty passed an instrument. Since then he had suffered from more or less inability to micturate. Fifteen years ago he had gonorrhœa. The patient is a big, burly, muscular fellow, of fair complexion and nervous temperament.

Mr. Collier was not able to see the case until twelve hours after admission. In the meantime hot baths and opium had been administered freely, but without effect, by the house-surgeon, and an attempt had been made with the catheter, but unsuccessfully. Owing to the delay the bladder was extremely distended, and the patient was suffering much from pain and nervous anxiety. He was now removed to the operating theatre, and a careful and prolonged attempt made with fine soft metal instruments, still without success. Judging that further delay was unwise, the bladder was aspirated with a long fine needle, the precaution being taken to pass the instrument well into the bladder in the direction backwards and downwards before removing the stylet. By these means some fifty ounces of urine were drawn off, with great relief to the patient. A dose of opium was followed by a good night and no pain or discomfort in the site of puncture. The temperature was normal. Next morning, no urine passing and the feeling of discomfort recurring, a hot bath, chloroform, and a second attempt with fine metal instruments was made. Catheterism having failed, it was decided to again aspirate and to relieve the bladder entirely by aspiration for the next few days, leaving the stricture absolutely alone. During five successive days the aspiration was repeated six times in all, very little urine during this time escaping by the urethra. On the fifth day chloroform was again administered, and after considerable delay and trouble a No. 1 metal catheter was passed into the bladder, and twenty-five ounces of fluid removed. The catheter was very tightly grasped, and required considerable traction or pressure to move it either in or out. The instrument was tied in and left *in situ* for four days. Afterwards an attempt was made to replace the No. 1 by a No. 2. The No. 2 would enter the stricture, but could not by any ordinary pressure be made to enter the bladder. No. 1 was now reinstated and left *in situ* for a week. The patient was comfortable during this time, and the temperature remained normal.

Sept. 14th.—The patient's temperature this morning at 8 A.M. was 100·6°. He seemed poorly. At 10·30 A.M. he had a severe rigor, and the temperature rose to 104·4°. Mr. Harper, the house-surgeon, attributing the rigor to the presence of the catheter, removed it, and administered ten grains of quinine.

Digitized by Google

15th.—The patient can pass some urine with much straining. Feels very uncomfortable. Temperature 102·6°.

16th.—Some pain and hardening was discovered in the floor of the urethra, two inches from the meatus.

17th.—The patient is very uncomfortable and the bladder full. Temperature 101·6°. After a hot bath and opium the distension of the bladder was relieved naturally.

18th.—The swelling under the penis, which was very painful and tender, was opened; pus came from the wound and also from the meatus.

9th.—Temperature normal. Great straining to pass a small quantity of urine; it mostly passes through the fistula; the bladder, however, does not fill.

The patient was now left completely alone to Oct. 1st, when a No. 1 silver instrument was passed with the same difficulty as on the first introduction. At 11 P.M., eight hours after the introduction, the patient had a rigor lasting an hour and a half, the temperature reaching 105·2°. Acting on instructions, the catheter was not removed by the house-surgeon, but large doses of quinine and hot drinks were administered.

Oct. 2nd.—At 10 A.M. the patient had another severe rigor; temperature 105·2°. At 4 P.M. there was another severe rigor, temperature reaching 105°. Mr. Collier removed the catheter.

3rd.—No further rigor; temperature normal; patient comfortable; urine passed frequently, but in small quantities.

4th.—Just one month after correct, careful, and assiduous treatment the stricture would only admit No. 1 instrument with difficulty, the introduction being invariably followed by severe rigor. The stricture was now also complicated by a penile fistula, through which most of the urine passed.

Mr. Collier now decided and explained to the patient that further attempts to dilate with the catheter were inadmissible and dangerous; that the proper course was to divide the stricture if possible from the inside, and, failing that, to cut through it from the outside. He fully understood the gravity of his case, but refused an operation, and was discharged on Oct. 14th and returned home. On Oct. 16th he returned and requested an operation.

On Oct. 21st Mr. Krohne procured a very small urethrotome of the Civiale pattern. After injecting the urethra with a 20 per cent. solution of cocaine, and subsequently with olive oil, Mr. Collier introduced his left forefinger into the rectum to the point of constriction, which could be easily made out in the membranous portion of the canal. With this finger the stricture was steadied. The urethrotome was next introduced, and an endeavour made to insinuate it into the stricture. By firm pressure, assisted by a peeling action of the left middle finger, the urethrotome was passed. The knife was now unsheathed, and the stricture completely divided in a direction upwards. The blade was again sheathed, reinserted, and again drawn through any opposing bands. There was free hæmorrhage. A No. 10 soft catheter was at once introduced without the slightest opposition, retained, and a suppository of half a grain of morphia placed in the rectum. No rigor or elevation of temperature followed the operation.

The subsequent progress of the case was most satisfactory. The fistula healed rapidly, and the patient left the hospital on Nov. 6th, just two months after his admission, with the calibre of the urethra completely restored, and feeling, as he expressed himself, "quite well, but weak."

Remarks by Mr. COLLIER.—This case is replete with points of interest, but two stand out more prominently than the rest. In the first place, six aspirations on five successive days were the whole and sole means of emptying the bladder of its contents. These tappings were not followed by the slightest pain or bad result. Aspiration of the bladder, if properly performed, is seldom dangerous. I have resorted to it on several occasions without the slightest bad effect. In the second place, although the presence of a No. 1 catheter in the urethra caused an intense rigor, the free division of the stricture was not followed by the smallest bad result.

MANCHESTER ROYAL INFIRMARY.

PERINEAL AND SUPRAPUBIC CYSTOTOMY COMBINED; REMARKS.

(Under the care of Mr. WHITEHEAD.)

J. C——, aged fifty-seven, engineer, was brought by Dr. Spearing, of Shaw, on Feb. 16th, 1887, and admitted on the following day suffering from severe pain in the region of the bladder, profuse hæmaturia, and incessant desire to micturate. The first indication of his present illness occurred ten months ago, when, without any warning or pain, "he passed three pints of what appeared to him pure blood." From that time the urine had almost constantly contained quantities of blood. He gradually became thinner and more feeble, and at the time of his admission he appeared in the advanced stage of malignant disease. The urine, on standing, gave a thick reddish-brown deposit, which on microscopic examination showed transitional epithelium, numerous fat-globules, red blood-corpuscles, leucocytes, crystals of uric acid, and oxalate of lime.

On Feb. 18th, an attempt was made, in the first instance, to explore the bladder by a lateral perineal cystotomy, but owing to the depth of the perineum the index finger only reached the entrance, but not the interior, of the bladder. Bidigital counter-pressure—one finger in the wound and the other hand above the pubes—demonstrated a solid growth associated with the right wall of the bladder. Suprapubic cystotomy was then performed, and the diagnosis which had previously been made of a malignant growth confirmed. No attempt was made to remove the tumour. The patient died on Feb. 24th, the sixth day after the operation.

At the necropsy a tumour was found which occupied the right half of the bladder and deeply infiltrated the surrounding tissues. The surface of the tumour was extensively ulcerated. The right kidney was atrophied, its parenchyma had almost entirely disappeared, whilst the pelvis was very much dilated. The corresponding ureter was much dilated, and its opening into the bladder impeded by the growth. The left kidney was considerably enlarged, but appeared healthy on section.

Remarks by Mr. WHITEHEAD.—Sir Henry Thompson has expressed his opinion that pain, and not hæmorrhage, is the usual premonitory symptom of malignant disease of the bladder; in this case, and in every other instance of malignant disease of the bladder coming under my personal observation, the reverse has been the case. The difficulty found in introducing the finger into the bladder through a deep perineum is unfortunately a condition not unfrequently met with. The obstructed ureter and atrophied kidney are an unusual result in malignant disease of the bladder, it being generally found that the growth does not encroach upon the ureters to the extent of total obstruction. The pain was considerably in excess of that generally met with in malignant disease of the bladder, but was no doubt due to the bladder being adherent on the right side to adjacent structures, thus preventing the muscles from exercising their contractile power, and causing the neighbouring parts to be dragged upon in the constantly recurring efforts to micturate. The fixed condition of the bladder was also responsible for another feature. The bladder was moderately distended previous to the operation, but none of the fluid came away when the perineal incision was made, nor even after the finger had passed through the prostate; but directly the bladder was opened above the pubes the fluid in the bladder rushed out of the perineal wound, as well as through the wound above the pubes, illustrating in a graphic manner the necessity and great advantage of counter openings when free drainage is the object desired.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Rectal Intussusception, due to a new growth; Excision of Intussusception; Enteroraphy; complete recovery.—Experimental Inquiry as to the best method of Enteroraphy.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

Mr. A. E. BARKER communicated a case of Intussusception of the Upper End of the Rectum due to obstruction by a new growth, in which complete recovery ensued, after excision of the intussusception and suture of the cut ends of the bowel. The case narrated is that of a married woman aged twenty-eight, who for sixteen months had noticed streaks of blood with her motions, and for eight months had been conscious of a foreign body in her rectum. Two or three months before operation the latter

Digitized by Google

had begun to prolapse at each stool with copious bleeding. There was much constipation, but there had never been any diarrhœa. On examination of the rectum in June, 1886, a mass of new growth was found surrounding nearly the whole of the apex of an intussusception of the rectum. The reflexion of the rectal wall could be felt about three inches from the anus, so that the apex of the mass belonged to a spot about six or seven inches from the latter. On June 9th Mr. Barker drew down the intussusception and operated as follows:—The left index finger was passed well into the intussusception and the two layers of bowel were pinched together beyond the growth between the finger and thumb. An ordinary sewing needle, carrying stout carbolised silk, was then passed through the two layers from the intussuscipient into the lumen of the intussusception and returned, including about one-sixth of an inch of bowel tissue. This loop was tied firmly, and another stitch was similarly introduced, about one-sixth of an inch from the first, and tied in the same way. By repeating this the whole bowel was encircled with a row of stitches well above the growth. When this had been done, a second row was similarly introduced about half an inch higher up. The whole intussusception was then cut away *en masse* immediately below the lowest row of stitches. Only one small vessel bled, and was tied; the rest of the cut surface was dry. The mass cut away consisted of a nodular mass of adenoid epithelioma, taking up about two inches of the bowel, and with a margin of healthy tissue above it. The patient's recovery was rapid and uninterrupted. A large motion was passed on the sixth day. The patient left the hospital about four weeks after operation feeling quite well. The rarity of intussusception of the rectum is discussed and some statistics are given. The rarity also of intussusception of the lower bowel produced by cancerous growths is alluded to, the author having only been able to collect eleven such cases. These are briefly described, six of them being either purely rectal or in the sigmoid flexure. Of these six, only four were operated on; the first two by Verneuil, but both with a fatal result. The next excision was performed by Kulenkampff with an ultimately good result, but a loop of small intestine had been opened in excising the intussusception and a provisional colotomy had to be done. The case now related is the fourth.

Mr. STANMORE BISHOP'S paper on the Results of an Experimental Inquiry as to the best method of restoring the Canal after removing Portions of the Small Intestine was communicated by Sir Spencer Wells, Bart. The question was discussed as to what an ideal suture should be, and reference made to all those now in use; the suture devised by the author was described. The results of some experiments on animals were detailed. A perfect method of enteroraphy requires: Absolute and perfect apposition. Restoration of the *status quo ante* of the calibre of the bowel. The surgeon must not leave any unnecessary sign of his interference behind him. The two serous surfaces must be brought face to face together. The various methods of enteroraphy were described and figured in a paper by Mr. S. Bishop in the *Medical Chronicle* of 1886.—Mr. T. HOLMES mentioned a case of intussusception in an infant which was constantly recurring and being reduced. The child died, and many polypoid tumours were found in the intestine besides the one that caused the intussusception.—Mr. HARRISON CRIPPS rather agreed with Mr. Holmes that cases of intussusception of the kind in question were not rare. Perhaps one case in six of annular malignant disease of the bowel was attended with an intussusception, which, however, did not advance and could not be pulled further down. Reference was made to the case of a lady in which the growth was with difficulty reached, the posterior part of the rectum having to be divided, and then, after some dissection, the whole growth, the size of a two shilling piece, was removed with both layers of the muscular coat, leaving only the peritoneum. He thought Mr. Barker's operation was one of extreme interest.—Mr. CHRISTOPHER HEATH was quite sure that any operation than that done by Mr. Barker would not have been successful. Neither the suggestion of Mr. Holmes nor of Mr. Cripps would have been sufficient, for the growth was a large, ragged, sessile tumour, nearly the size of the palm of the hand. He was agreeably surprised to find what an excellent recovery had followed the operation. Such an operation seemed to show that greater liberties might be taken with the mucous membrane of this part than had hitherto been supposed. Mr. Whitehead's method of treating piles also pointed to the same conclusion. How would Mr. Barker deal with a case which could not be drawn out of the anus? With a growth higher, up would laparotomy or what operation be best?—Mr. A. E. BARKER said the growth infiltrated the coats of the bowel, rendering a mere excision of the growth impossible. To dissect off the growth would be an unsatisfactory method in the case of a malignant neoplasm. It would be preferable to remove the whole of the intussusception. In reply to Mr. Heath, he said he should certainly perform laparotomy and excise the whole mass of the intussusception. He would search for the upper part of the intussusception and employ Czerny's suture for a row of stitches, and afterwards cut off the intussusception, thus imitating nature's method of sloughing. He thought that there was a good deal in Mr. Bishop's method of suture.—Mr. F. TREVES said that Mr. Barker's case was the most deliberate, complete, and successful operation of the kind on record. He made three classes of cases in which intussusception and cancer become combined. The first was an annular cylindroma forming an obstructing ring, and this forms a commencing intussusception. The second kind was made up of cases of chronic intussusception which develops into an epithelioma. The third class was composed of cases where an ordinary polypus, having produced an intussusception, becomes a cancerous growth. Mention was made of the case of a woman, aged forty, with chronic intussusception, in which unsuccessful attempts to draw it down to the anus were followed by removal with a galvanic wire; the lumen was restored, and the patient remained comfortable for a while. The return of obstruction was relieved by a lumbar colotomy, and no less than eleven polypi were removed at the operation.—Sir SPENCER WELLS thought that as Mr. Bishop's knots and suture did not irritate the peritoneum, and when separated the stitches fell into the cavity of the bowel, a great advance was made in abdominal surgery. He considered that the result of Mr. Bishop's experiments was a complete argument to those who objected to the funds of the Royal College of Surgeons being employed for legitimate vivisection.—Mr. CROFT compared the suture recommended by Mr. Bishop with that of Lembert, and thought that it might have disadvantages, for the stitches were so close together that the suture might amount to a circular stricture of the bowel, and possible cutting off of the blood supply. He would be sorry if everyone set this suture down as an absolutely unobjectionable one. The tissues operated upon were those of healthy dogs, whereas in diseased men and women the tissues might prove less tolerant of the suture. Whether the latter fell away into or outside the intestinal canal he considered was a matter of small moment. He admitted that the suture had some advantages.—Mr. TREVES had tried every suture on dogs some years ago, and came to the conclusion that the Czerny-Lembert suture was the most suitable. Time was a great element in enteroraphy, and the old suture was readily manipulated. The bowel of the dog was hard and tough, unlike the thin delicate bowel of the human being. If the stitches were applied tightly enough to bring the bowel well together, the danger certainly would exist of sloughing of the margin of the bowel. Travers' experiments were performed with string and coarse dressings, which sufficiently explained his disasters. — Mr. KNOWSLEY THORNTON said that Mr. Bishop's suture did not favourably compare with Lembert's, for the knots within the bowel were favourable to the absorption of septic material, abundance of opportunity for which would exist, especially in the case of a diseased bowel. He agreed with the remarks of Mr. Treves as to the constriction of the bowel.—Mr. R. BARWELL had employed Lembert's suture in a boy aged seven. The whole of the suture was neatly enveloped in lymph.—Mr. BARKER asked how long the thread was which filled the needle. Passing so many times through the mucous membrane, the thread must become very septic.—Mr. T. BRYANT asked how Mr. Bishop tied the last knots.—Mr. CHARLES JENNINGS did not understand Mr. Treves's objections to experiments on living animals. He (Mr. Jennings) had used cylinders of cocoa butter and gelatine, so as to maintain the lumen of the bowel whilst the suture was being inserted.—Mr. BISHOP, in reply, thought the time of exposure of the bowel far more important than the mere duration of the operation. Experiments could only be satisfactory if performed on living animals. He did not use one thread for the whole operation, but as many as might be necessary, and by reef-knotting the fresh thread on to one end of the single threads of the suture.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, May 4th, Dr. John Williams, President, in the chair.

Uterine Appendages.—Mr. LAWSON TAIT showed a series of specimens removed on account of inflammatory disease.

Malformation of the Fallopian Tubes.—Mr. ALBAN DORAN exhibited this specimen, in which there was an accessory ostium surrounded with fimbriæ.

Spinal Meningocele.—Dr. JOHN PHILLIPS showed, for Mr. Reginald Clarke, the head of a seven months fœtus, in which there was dystocia, owing to a meningocele between the axis and occipital bone. The child presented by the breech.

Fibro-myoma of the Ovary.—Dr. CARTER said that this tumour, which weighed 10¾ lb., had only been noticed for six months. The patient had made a good recovery.

A pair of Midwifery Forceps were shown by Dr. PARAMORE, for Dr. Haslam, with a lateral hinge in the handle of the upper blade.

A Speculum was exhibited by Mr. BUTLER-SMYTHE which folded like a tongue depressor.

Hæmorrhagic Parametritis.—Dr. MATTHEWS DUNCAN related three cases of severe bleeding in patients with Parametritic Abscess. In the first case the bleeding occurred on opening the abscess, and was easily restrained; the woman recovered. The bleeding was probably only a profuse oozing. The second case he did not see; the bleeding was rapidly fatal and flowed through the bladder, the abscess having spontaneously opened into that viscus. In the third case, also fatal, the bleeding occurred in repeated flows through the bladder, along with pus and sloughs. The bleeding arose from gangrene laying largely open the external and internal iliac veins at their junction. This case he regards as one, not of ordinary parametric abscess, but of progressive gangrene of cellular tissue. Of this latter disease he has recorded a case in an appendix to his work on "Perimetritis and Parametritis."—Dr. GRAILY HEWITT referred to the particulars of a case he had published, and which Dr. Matthews Duncan had mentioned in his paper. It was entirely due to physical injury, and was not at all analogous to the cases of Dr. Matthews Duncan.—Dr. WILLIAM DUNCAN had seen two cases in which, after bursting of the abscess, there was oozing of blood for several days from the pyogenic membrane lining the abscess cavity. He thought that it would have been more correct if Dr. Matthews Duncan had given the cases as hæmorrhage into the sac of a parametric abscess, and deprecated the use of the title "hæmorrhagic parametritis."—Dr. GALABIN had met with a case in which fatal hæmorrhage into a pelvic abscess occurred. The case was originally diagnosed as one of retro-uterine hæmatocele. Suppuration occurred, and discharge through both bladder and rectum. After three months, erysipelas occurred about the vulva, and fatal hæmorrhage into the abscess cavity. Extensive burrowing and sloughing in the pelvic cellular tissue were found at the necropsy.—Mr. LAWSON TAIT had never met with any such cases as those described by Dr. Matthews Duncan, and thought that they ought to be dealt with by abdominal section before such disasters occurred. Mr. Tait thought the title of the paper should have been "Parametritis ending fatally by Hæmorrhage."—Dr. MATTHEWS DUNCAN thought that the title was of no moment, whether hæmorrhagic parametritis or parametritis with hæmorrhage. He knew no reason to regard extravasation of urine as the cause of sloughing, and in a very large number of cases of these abscesses discharging through the bladder he had never met with any evidence of extravasation of urine into the abscess cavity. It might occur, but he knew no evidence of it.

The Frequency of Pathological Conditions of the Fallopian Tubes formed the subject of a paper by Dr. ARTHUR H. N. LEWERS, and was the outcome of observations on the pelvic organs in a series of a hundred cases in the post-mortem room of the London Hospital, made with the view of assisting in the determination of the frequency with which dilatation of the Fallopian tubes—hydrosalpinx, pyosalpinx, and hæmatosalpinx—occurs among the general population. Recently Dr. Henry Coe, in his paper, "Is Disease of the Uterine Appendages as frequent as it has been represented [illegible] *of Obstetrics*, June, 1886) said: [illegible] tubes is far less frequent than is [illegible]. Others, on the contrary, believed these conditions to be of frequent occurrence. Cases where the contents of the dilated tubes were not distinctly purulent, or were not composed of blood, were classed by Dr. Lewers as hydrosalpinx. Disease of the Fallopian tubes, restricting the expression to pyosalpinx, hæmatosalpinx, and hydrosalpinx, was met with in seventeen cases out of one hundred examined. A detailed description of each specimen was given in the paper, which included also a table classifying the chief points of interest in these seventeen cases.—Dr. GALABIN thought this communication was of very great value as an addition to the evidence on the subject by Dr. Kingston Fowler. He wished to ask whether the 100 cases recorded were consecutive or selected, as he thought that 17 per cent. was a large proportion of cases of distension of the Fallopian tubes. In 302 necropsies of women above the age of puberty at Guy's Hospital the pathologists had only found twelve cases of distension of tubes, and two of these were very trivial. This was a proportion of only 4 per cent. There was only one case of pyosalpinx and a doubtful case, the pathologist being uncertain whether two suppurating sacs were tubes or ovaries; the ovaries could not be found. There were fourteen cases of chronic inflammatory disease about the Fallopian tubes without distension. Of the whole twenty-six cases, it was probable that in seven pelvic inflammation was indirectly the cause of death through the medium of general peritonitis, intestinal obstruction, or in other ways. These included the two cases of pyosalpinx, one of hydrosalpinx, and four of chronic inflammation without distension. Thus, in 302 cases there were of chronic inflammatory disease about the tubes 9 per cent., distension of tubes 4 per cent., death indirectly in about 2 or 3 per cent.—Mr. LAWSON TAIT spoke in eulogy of Dr. Lewers' paper. He found the conclusions drawn from the post-mortem room as regards causation, progress, prognosis, and treatment identical with those which he had been preaching for about ten years on the basis of clinical experience. He confessed that it was somewhat a staggering thing to find 17 per cent. of the women who died in the London Hospital suffering from tubal disease, and this did not include those cases which suffered the most, in which there were adhesions between the ovaries and tubes to the surrounding viscera, more particularly the peritoneal layer lining Douglas's pouch, resulting ultimately in complete retroversion of the uterus with its appendages, and forming one of the most dreadful conditions which the gynæcologist had to deal with. When removed, it was difficult for an unskilled pathologist to see anything the matter with them. Dr. Lewers had not included such cases, and they must have been numerous. He thought the explanation of the higher percentage at the London Hospital and the small group at Guy's must be due to locality, and that gonorrhœa was more common amongst the poor at the East-end than on the south side of the river. At the out-patient department at Birmingham 10 per cent. of the women who applied for relief suffered from chronic inflammatory disease of the uterine appendages. All these did not require operation. The most staggering conclusion to be derived from Dr. Lewers paper was the enormous fatality of these diseases. At the London Hospital the death-rate was 24 per cent., while at Guy's it would appear to be 25 per cent. For years Mr. Tait had been arguing in favour of operation in order to relieve suffering, but when the pathologists at the London, Guy's, and Middlesex Hospitals showed a death-rate between 24 and 50 per cent., the cry for relief by operation was one which could not be gainsaid. His own results showed that these cases could be relieved by operation, with a mortality not exceeding 2 or 3 per cent. The question as to the sterility caused by these diseases might be settled by ascertaining the period between the occurrence of death and the birth of the last child. Mr. Tait agreed with Dr. Lewers that hydrosalpinx seems to precede pyosalpinx.—Dr. HORROCKS was surprised at the large percentage of disease of the Fallopian tubes shown in Dr. Lewers' table of cases. He found that in many cases the disease began in the ovary and glued the fimbriated extremity to itself, which led to pathological changes in the tubes. In some cases the affection spread from the vagina to the uterus and from the latter to the tubes. In all his cases there was peritonitis, but in nearly every instance it was [illegible] process indicated only by old [illegible]. Mr. [illegible] noted that [illegible] [illegible] disease [illegible] [illegible] through the uterus so as not to [illegible]

Digitized by Google

not likely that it escaped through the ostium into the peritoneal cavity, else hydroperitoneum would be more frequent, as he had pointed out in his paper on Papilloma of the Tube. The severe forms of tubal disease with local peritonitis showed how the tubes were a highway from the exterior into the peritoneum. Their frequency amongst the East-end women suggested that they arose more from extension of neglected leucorrhœa and gonorrhœa than from sounding or syringing. Disease of the tubal mucous membrane was more probably caused by the passage of fluids upwards than by extension of inflammation. Extension might occur, but mucous inflammations were generally localised in the genital as in the respiratory tract.—Dr. IMLACH regarded Dr. Lewers' paper as important, and trusted the investigation would be continued, and that pathologists would scrutinise the ovaries and tubes as carefully as they did other organs. The gonorrhœal origin of these diseases was often assumed. He had examined a large number of women in the lock hospitals, but had not found a single example of pyosalpinx amongst them. The question of etiology was important, and could only be settled by clinical investigation of a large series of gonorrhœal patients.—Dr. MATTHEWS DUNCAN expressed his sense of the great value of Dr. Lewers' paper, but felt the want of further information regarding the cases. He wished for information as to the symptoms, if any, caused by the pathological conditions. It was probable that these pathological conditions were obsolete and evidence only of long past disease. This view was confirmed by the ages of the patients. Mr. Tait had said that in his practice the average was twenty-seven to thirty, and Dr. Lewers' cases were above forty on an average, and many quite old. Dr. Matthews Duncan was not astonished at there being evidence of disease in 17 per cent. of the post-mortems, for he had long known that evidence of past or present disease in the region of the uterine appendages was a very frequent occurrence.—Dr. WILLIAM DUNCAN thought it most important that out of the seventeen cases reported, fourteen were over forty years of age, and in only one case were definite symptoms of pelvic mischief given, while almost all died from diseases not attributed to tubal mischief, showing the fallacy of the view that most cases require laparatomy.—Dr. LEWERS, in reply, said that the cases were as nearly as possible consecutive, and that the inquiry lasted thirteen months. There were many cases showing more or less extensive old adhesions not included in his list. He did not think gonorrhœa was more common at the East-end than elsewhere in London, and many of the cases at the London Hospital came from the adjoining districts. He thought hydrosalpinx and pyosalpinx were stages of the same disease, and the cases in his table confirmed this to a great extent. If further investigation should establish this view, and that pyosalpinx has a mortality of 40 per cent., we shall not be able to resist the conclusion that dilated tubes should be removed. None of the seventeen cases of dilated tubes came from the obstetric wards, though some of the 100 cases examined came from those wards.

OPHTHALMOLOGICAL SOCIETY.

Franklin's Spectacles.—Fatal Meningitis after Excision of Suppurating Globe.—Insertion of Artificial Globes into Tenon's Capsule after Excising the Eye.—Night-blindness.—Complete Self-enucleation of Eyeball.

AN ordinary meeting of this Society was held on the 5th inst., Mr. J. Whitaker Hulke, F.R.S., President, in the chair. The President announced that Dr. Samelson of Manchester, had presented a volume of letters of von Graefe to the Society.

Mr. BRUDENELL CARTER showed a pair of Franklin's Spectacles for use after Cataract Extraction. They were made by cementing two small semicircular plano-convex lenses upon an oval of plane glass. Thus, both near and distant vision was afforded, and the spectacles were not heavier than ordinary spectacles. Messrs. Baker, of 244, High Holborn, were the makers.

Messrs. CRITCHETT and JULER showed a case of Peculiar Dotted Appearance of the Fundus of the Right Eye, whether choroidal or retinal they could not say, nor whether it was congenital or acquired; syphilis was probably not operative. There was haziness of the vitreous of the other eye. They also showed a case of a young woman with a rare form of Pigmentary Change in the Retina.—Mr. NETTLESHIP asked how long the condition had probably lasted in the first case?—Mr. JULER said there was slight myopia, but no history of special failure of vision.—Dr. HILL GRIFFITHS mentioned a case of minute dotted appearance of the fundus about the macula in a woman whose sight was defective from abuse of tobacco, but as her sister had a similar change in the fundus he regarded the lesions as of congenital origin.—Mr. W. H. JESSOP said there was pigment in front of the large vessels in the second case, and therefore in the retina.—Mr. JULER admitted that the pigmentary layer was much affected in places.

Mr. ADAMS FROST showed a case of Cystic Tumour in the Orbit of a woman aged thirty-five. It was of two years' duration, the eyeball being merely prominent till six months ago, when a soft swelling appeared at the upper and inner angle of the orbit beneath the skin of the upper lid; the cyst was punctured but yielded nothing.

Mr. ERNEST CLARKE showed a set of Artificial Eyes made by Maw, Son, and Thompson, at the inexpensive cost of 3*s.* each.

Mr. W. J. COLLINS showed a case of Cholesterin in the Vitreous in a man aged sixty-six, probably primary, the right eye being alone affected. Such a condition might disappear according to von Graefe.

Mr. W. J. COLLINS also exhibited a living specimen of Exophthalmos with Opacities of the Lens in a young woman, with marked palpitation but no goitre, though a small one had been present a year ago. Von Graefe's and Stellwag's signs were absent.—Mr. NETTLESHIP said there was slight ptosis of right side, in which the disease began, the reverse of what was usually seen.—Mr. COLLINS thought the ptosis might be due to congestion, for it was variable in degree.

Mr. LANG read notes of a case of Fatal Meningitis following excision of a suppurating globe, and causing death in forty-eight hours. The necropsy revealed extensive suppurative meningitis.

Mr. LANG also read a paper on the Insertion of Artificial Globes into Tenon's Capsule after Excising the Eye. He had employed this plan after finding that Dr. Mules's operation for evisceration and an artificial vitreous was unsatisfactory. The operation consisted in inserting a hollow globe of glass, celluloid, or silver into Tenon's capsule, and then closing the capsule by a set of deep sutures, and the conjunctiva by a superficial set, both of silk; the deep ones were not removed. A horse-hair drain placed under the deep sutures and an iced pad to the lids prevented pain and swelling of the lids and conjunctiva. In sixteen cases not one had suppurated; this was probably due to the antiseptic precautions which were taken—namely, to irrigate the conjunctival sac before excising the eye, again after the excision (and this brought Tenon's capsule plainly into view), and finally when the operation was completed. He advocated the operation, as it had all the advantages of Dr. Mules's operation without any of its disadvantages.—The PRESIDENT had never met with a fatal case after excision of a suppurating globe. Was extension of the inflammation brought about by the application of a too firm compress? Fluids in the orbit might conceivably in this way be driven back. Would it not be better to treat such a case as in an ordinary wound, and leave the orbit quite free from pressure?—Mr. NETTLESHIP remarked that the meningitis might have preceded or accompanied the suppuration of the eyeball, and he therefore asked whether there was any fever before the operation or other indications of a similar significance.—Mr. BRUDENELL CARTER said that Sir Wm. Bowman had thirty years ago condemned the extraction of the capsule of the lens from the eye as a certain cause of cyclitis &c. In operation on the eye he always soaked his instruments in alcohol, a useful precaution against septic infection, he believed. Following von Graefe, he never excised an eye in a case of suppuration.—Dr. BRAILEY was of opinion that evisceration was the best method of treatment of suppurating eyeball. The occurrence of suppuration was, perhaps, not often due to inoculation with germs on instruments, but had more to do with the general condition of the patient. He thought it was more reasonable to suppose that a more beneficial effect and less chance of spread of the suppuration to the meninges would be obtained if the sclerotic were left, than if the capsule of Tenon was the only barrier.—Mr. ADAMS FROST confirmed all Mr. Lang had said in favour of his operation as compared with that of Dr. Mules. His own operation had not been so successful as Mr. Lang's.

Digitized by Google

His plan was to unite the muscles with Tenon's capsule and the conjunctiva over the globe; the hæmorrhage was sometimes very troublesome. He thought that removal of the sclerotic was an additional safeguard.—Dr. MULES had had upwards of one hundred cases of evisceration without any cause for anxiety; the cases were kept in about twelve days. There had been no sympathetic disease, nor had there been any difficulty in cleaning out the interior of the globe.—Mr. JESSOP thought that the capsule of Tenon would get worn away by the foreign body; the sclerotic (as in Dr. Mules's operation) was the only tissue in the body of sufficiently low vascularity to withstand the irritation of a foreign body.—Dr. LITTLE said that he sometimes enucleated and sometimes eviscerated; the latter when he had good reason to believe that the back part of the eye was not involved in the disease. He did not use or advise the employment of an artificial vitreous for fear of irritation resulting.—Mr. F. R. CROSS said that evisceration was a not altogether successful operation, for it was uncertain whether a sinus or fistula might appear after the introduction of the artificial vitreous; and the thin conjunctival membrane between the artificial vitreous and the glass eye would be sorely tried. He concluded that the old operation was the best still, especially if some means could be devised to keep the lower eyelid firmly against the glass eye.—Mr. BRUDENELL CARTER had performed Dr. Mules's operation about twenty-five times. He had seen difficulty arise from the wound not uniting properly. He thought it an excellent and safe operation. — Mr. NETTLESHIP had performed Mr. Frost's operation five times; twice successfully, but in one of these the globe had become displaced.—Mr. LANG, in reply, said the lens capsule was very tough and quite loose, and required no force in its extraction. He did not believe in the absorption of soft tissue by a foreign body. Gaping of the wound was due to the use of too large a globe.

Mr. NETTLESHIP narrated four cases (in two families) of Night-blindness of long standing, and apparently at present not increasing, in which a number of very small, scattered, white spots were present at and behind the equator of the fundus, evidently caused by deposit, not by atrophy. In none of them were there any of the appearances of common retinitis pigmentosa, though there was pigment disturbance of a somewhat different kind towards the periphery in some of them. The patients were grown-up girls.

Mr. MACKINLAY narrated a case in which a woman had wrenched out her left eye with a meat-hook. She was thirty-nine years of age at the time, and had had several children in rapid succession. She was suckling a baby three months old, and had been much depressed for three or four days before the occurrence. The optic nerve had been snapped off close to the commissure. She made a rapid recovery. The only case he knew of was one recorded by Mr. M'Hardy in the last volume of the Society's Transactions.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

TUESDAY, MAY 10TH.

SIR HENRY ACLAND, PRESIDENT, IN THE CHAIR.

AT the meeting of the General Medical Council on Tuesday last, the PRESIDENT delivered the following opening address:—

At the close of the last session the Council did me the honour of desiring that I should retain office until we could with advantage meet to further consider the relation of the Apothecaries' Societies to the Royal Colleges of Physicians and Surgeons in England and Ireland, and the consequences which would arise should they fail respectively to combine for examination purposes. I find myself, therefore, once more called upon by your favour to open another session of the Council. In the discharge of that duty I shall state very shortly the chief business which is before the Council. I shall offer a summary of the proceedings which relate to the action of the Colleges and the Apothecaries respectively, and then, before I retire, shall request you to permit me, as my last act, to join you in recording the sense we all have of the blessings this country has enjoyed during the eventful reign of the Queen and Empress of this united empire. First, then, and briefly, as to the business, exclusive of the combination question. This is already for the most part set forth in the programme now on the table. Through the activity of your committees, their reports afford ample scope for prolonged attention, but also through the carefulness of the reports each subject can be rapidly, as well as clearly, dealt with. It would be an improper employment of time were I to give any account of the several reports on procedure, income and expenditure, or practical education, in the consideration of which I shall be unable to share. The Council will doubtless desire that I shall pass at once to the question of the combination of the three licensing corporations in England and Ireland respectively. First, I would ask that the several communications from the four Colleges and the Societies of Apothecaries, which are upon the programme, may be received and entered upon the Minutes. I will offer such short commentary upon them as may lay the whole case, as I understand it, clearly before you. I will then report the little that it has been in my power to do in furtherance of the Council's wishes. First, as to the case of England. The letter which was read to you at the last meeting was forwarded to the four Colleges on February 25th. Replies were received from the Royal College of Physicians of London on March 23rd, and from the Royal College of Surgeons of England on April 2nd. No desire was expressed by either of the Colleges for an interview. It was clear from semi-official information which I received that if an interview were obtained with the College of Surgeons it would be useless for the object of the Council. I did not therefore press it. With respect to the College of Physicians the case was different. Having been for nearly forty years a Fellow of that body, I was, in my judgment, bound in that capacity to attend the meeting when the subject would be discussed. Accordingly, on March 21st this was done. What passed I am not at liberty to relate. Discussions are held to be *secreta collegii*. But I may just say that it seemed to be a duty to endeavour to disabuse the College of a charge which had been privately made to me, that, in the judgment of many Fellows, the Medical Council had gravely outstepped its duties by addressing the College on the subject. As a Fellow, I do not hold that opinion; whether it was largely entertained, I cannot say. That it was held, by whomsoever held, on an imperfect conception of the position of affairs, cannot reasonably be doubted. Since the time when the Colleges declined to admit the Apothecaries' Society, that body had applied to the Medical Council for examiners under the Medical Act, 1886. The Council, as well as the Colleges, had at various times declared in favour of union between the licensing bodies in England, inclusive of the Apothecaries' Society. If there was any chance still left of union, the Council was clearly bound not to appoint the examiners and thus erect the Apothecaries at once, and *de novo*, into an independent licensing corporation. It was a case in which precipitancy was to be with the utmost care avoided. We were deciding upon a momentous education question of the future. The answer which you have now received must be accounted as final. A simple question therefore remains. The Apothecaries apply again to you through a new motion (Programme, No 12) for examiners. To this application a reply must now be given. An endeavour will be made to traverse the direct answer by means of a motion by Professor Struthers. This motion makes it my duty to make certain statements for the information of the Council. Very opposite opinions have been pressed upon me since we last met—as, for instance: (1) That the Council should certainly refrain from appointing the examiners, and should leave the onus of the decision to the Privy Council. (2) That the Council is bound, both in honour and by the principles of law, to carry out the alleged intention of the Legislature by the Act of 1886 and to appoint examiners. (3) That it will be injurious to the public interest that the Apothecaries should continue to exist as an examining body. (4) That it will be a real advantage to retain them side by side with the two corporations and the Universities, in order that excessive and unnecessary scientific examinations may not be imposed on every medical student. I have noted that some who used to wish the Apothecaries to be "extinguished" now hold the opposite opinion. (5) That if the Medical Council do not grant the examiners, the Privy Council will certainly not override your decision. And, lastly, (6) that the Privy Council will certainly, in the case of your refusal, direct you to appoint examiners, and, if you then decline, will

Digitized by Google

appoint them against your judgment. If this be so, the Privy Council will be acting in the unquestioned exercise of its powers under Clause 19 of the Act of 1886. In what proportion these opinions, and others which have been pressed upon me, weighed with the English Colleges cannot be stated, since they do not assign their reasons for not consenting to form one Corporation Examining Board for England, and in this simple way bring to a close a long and tedious discussion. To you, therefore, or to the Privy Council, is left the decision whether to perpetuate or to extinquish an examining body which for seventy years has rendered the State acknowledged services. I should not have ventured to trouble you with these divergent and hearsay statements but as an introduction to what follows. Since we parted, it appeared to me to be a duty to learn, as far as I could, the legal view of our position—subject, of course, to the uncertainty of all opinion not resting on judicial decisions in a court of law. I gather that the Council would probably be advised that they will fail in a statutory duty if they refuse to appoint the examiners. It is true that under the Act of 1886 the Council has power to refuse. "It shall be lawful for the General Council, if they think fit, on the application of (a) corporation, to appoint any number of examiners to assist at the examinations" (Clause 5). But then, by Clause 19, "*if it appears to the Privy Council*" that "occasion has arisen for the General Council to appoint assistant examiners," "the Privy Council may notify their opinion to the General Council"; and if the General Council fail to comply with any "directions of the Privy Council" relating to such notification, the Privy Council may themselves give effect to such directions." The Medical Council is therefore powerless to prevent the appointment of examiners. Its decision must rest, not on the question whether the new examining board of the Apothecaries would be adequate or inadequate, but on the general question of policy or vested interests in respect to an old corporation. It is clear that the Legislature has carefully guarded these interests by giving a right of final appeal to the Privy Council. By refusing examiners, the Medical Council would propose a policy, but that only provisionally. If it grant examiners, it becomes the complete guardian of the examinations, because it would both appoint the examiners and send its inspectors. It cannot therefore be alleged that the Apothecaries' examinations will be inadequate, if they continue to exist. It may be said they are unnecessary. The Legislature has implied that the Apothecaries have rights. If we refuse these, they appeal to the Privy Council. That body will, on a review of the whole case, interpret, as it sees fit, the intentions of Parliament by the Act of 1886. As regards the Apothecaries in Ireland, the case may be more shortly stated. A direct legal issue has been raised by the College of Physicians. You have before you the statement of the College of Physicians of Ireland (March 19th and 21st), the letter of the College of Surgeons (March 24th), and recently a further letter from the College of Physicians, dated April 26th, and opinions of counsel forwarded by the Apothecaries' Society of Ireland, dated May 5th. From these documents three special conclusions may be drawn:—1st, that it (the College of Physicians) uncompromisingly decides against any combination, alleging that the Apothecaries cannot grant a licence in medicine, and therefore no body can combine with the Apothecaries; 2nd, that they therefore dispute the power of the Medical Council to grant supplemental examiners to the Apothecaries; and 3rdly, that the College of Surgeons, in its judgment, propose to incorporate the Apothecaries with themselves for examination purposes, without the Physicians, rather than that the Council should give the Apothecaries a permanent and independent position by granting the examiners. It is here necessary to observe that the Council has before it the opinion of the Attorney-General, the Solicitor-General, and Mr. Muir Mackenzie, that under the Medical Act of 1886 the licensing bodies can combine without the sanction of the Medical Council, and not, as heretofore, under conditions to be approved by you. By this opinion the Surgeons and Apothecaries of Ireland can combine, if the Apothecaries can combine at all, without your consent or that of the College of Physicians. I cannot conclude this sketch of an important subject without thanking the Irish members of the Council for much assistance in this matter. I need not longer detain the Council. There is much to be considered during this session, and my medical advisers forbid me to share it. Indeed, I feel assured that, in your interest, I should, for the last time and with deep regret, bid you farewell. This I do with an earnest prayer for the steady progress of the scientific, humane, and national work which Parliament has laid upon you. I trust, however, you will allow me, before I quit the chair, to propose for your consideration a humble address to the Queen. The two surviving members of the original Council may thus join you in discharging a welcome and touching duty to a Sovereign who is full of sympathy for the sufferings we have to prevent and to alleviate, and greatly beloved by all her loyal people. (Applause.)

Mr. MARSHALL, in moving that the President's address be entered on the Minutes, said he was sure the members would desire to express to him their extreme pride and gratification as to the manner in which he had discharged the duties of his office for so many years, and their deep regret that his physical health should compel him to relinquish his post. The address which he had just delivered would be an excellent guide to the Council through the labyrinth of questions which seemed to be pressing urgently for solution.

Sir WILLIAM GULL claimed the privilege of seconding the motion. He had known the President forty-eight years, and he had never met with anyone who had so thoroughly devoted himself to duty—to which, indeed, he had sacrificed every other consideration.

The motion was unanimously agreed to.

Mr. SIMON moved that the following address be engrossed and presented to Her Majesty:—

To Her Most Gracious Majesty Queen Victoria, Queen of Great Britain and Ireland, Empress of India.

May it please your Majesty,—We, the General Medical Council of Education and Registration of Great Britain and Ireland, humbly tender our loyal congratulations to your Most Gracious Majesty on the approaching completion of the fiftieth year of your Majesty's reign. Having been appointed by Act of Parliament to take steps for enabling your Majesty's subjects to distinguish between those who are, and those who are not, qualified by education and character to practise medicine in your dominions, we have had the opportunity of noting the progress which has been made during your Majesty's reign in the science of medicine, especially in its bearings on the health of the nation. The progress of education and the improvements in the practice of all branches of medicine, civil and military, have been great during the last fifty years. Towns have been rendered more healthy; rural dwellings have been improved; dangerous occupations supervised; medical officers of health and public analysts appointed; excessive hours of labour regulated; the treatment of the sick poor in our workhouses amended; and asylums for mental diseases carefully organised. In all these improvements medicine and medical education have had a large share. To these subjects the lamented and illustrious Prince Consort gave earnest attention, as evinced by the interest he took both in the erection and administration of model dwellings and hospitals—institutions which have also been the objects of your Majesty's solicitude and sympathy. We desire further to express our sense of the obligation under which the nation lies to all the members of your Royal House, who, treading in the steps of their Royal parents, have constantly shown, by numerous acts, their desire to promote the sound progress—scientific, educational, and practical—of every department of rational medicine. For these, amongst other reasons, bearing on the general welfare, we have special cause to join our fellow-subjects throughout the empire in thankfulness to the Almighty for the blessings of your Majesty's reign. We fervently pray for your Majesty's continued peace, well-being, and happiness.

We have the honour to be your Majesty's dutiful and loyal subjects.

Dr. H. WATSON seconded the motion.

Sir WILLIAM GULL, in supporting the motion, said that Her Majesty not only deserved the respect and affection of her subjects, but she had special claims on the medical profession, to which she had ever been thoroughly loyal, never countenancing quackery or anything leaning towards irregular practice.

The motion was agreed to.

The PRESIDENT then retired from the chair, expressing his earnest desire for the progress and well-being of the Council as long as it and England lasted.

Dr. QUAIN was requested to occupy the chair during the discussion on the election of the President. He said he was sure that the Council would desire to pass a hearty vote of thanks to the retiring President for his long and valued services.

Sir WILLIAM TURNER seconded the motion. The late President, he said, had always performed his duties in the spirit of a kindly gentleman, never once losing his temper.

Mr. MACNAMARA desired, as one who had perhaps tried the President's temper sorely, to support the motion, and suggested that an address should be drawn up and presented to him on his retirement.

This was agreed to, and a committee was appointed to draw up the address.

Dr. QUAIN said that the duty now devolved upon the Council of electing a president from among themselves, as

Digitized by Google

required by the Act of Parliament. There were no rules given for the election, and the Council would have to decide whether it should be by ballot or otherwise. A precedent would thus be established to regulate future elections.

Strangers were then requested to withdraw, and the Council deliberated in private on the subject of the election.

On the readmission of strangers, Dr. QUAIN intimated that Mr. Marshall had been unanimously elected as President of the Council.

Mr. MARSHALL, in taking the chair, expressed his thanks for the distinguished honour conferred upon him. When he remembered the names of his predecessors he felt the serious responsibility of his office. He was now in the peculiar position of being one of themselves, and it might be supposd that, as the representative of a particular body, he might be liable to swerve from the line of duty. He was quite sure, however, that that body would feel itself disgraced if he allowed himself to have his conduct influenced or modified in the least degree by the circumstance of his connexion with it. His duties would have relation chiefly to the mode in which the business of the Council was conducted, and the object of the president of any public body should be, on the one hand, to protect individual members, and, on the other, to maintain his own authority in the chair. It was quite possible that those two conditions might be excellently maintained; and it would be his endeavour not only to throw his whole soul into the affairs of the Council, but to conduct the business (according to the Celsian maxim with regard to a surgical operation) *cito, tuto, et jucunde.*

Sir Wm. Turner was then appointed a member of the Executive Committee in the place of Dr. Haldane, and Mr. Wheelhouse in the place of Mr. Marshall.

On a motion for entering on the Minutes the usual statement of the degrees, diplomas, and licences of the candidates for commissions in the medical staff of the army, who on February 14th and following days presented themselves for examination,

Dr. MCVAIL pointed out that the holders of English diplomas appeared to have been much more fortunate than the holders of Scotch and Irish diplomas, and suggested that the circumstance might perhaps be accounted for by differences in the examinations in the different bodies. He thought it was desirable to ascertain from the Directors-General of the Army and Navy Medical Departments what conditions regulated the numbers in the column "qualified, but not successful." Last year, he said, it appeared that out of six licentiates of the University of Edinburgh two were appointed to vacancies and four were actually rejected

Dr. QUAIN said that any body that considered itself aggrieved could make application to the Directors-General, but that it was not the duty of the Council to interfere in the matter.

Sir DYCE DUCKWORTH said that the holders of the qualifications referred to must also have had other qualifications, and that no definite conclusions could be drawn from the figures given, unless they were carefully read. The matter might be referred to the Executive Committee for inquiry.

Sir WM. TURNER said that, as representing the University of Edinburgh, he would bring the matter before that body, but it was not a subject to be taken up by the Council. It was satisfactory to observe that out of seventy-three candidates only three were rejected.

Mr. B. CARTER said that Sir Thomas Crawford had told him that the examinations of candidates for examination during the present year had been exceptionally good, and that many more vacancies were filled in consequence.

Dr. DUNCAN said he sympathised with Dr. McVail's views, and thought it desirable to know what were the conditions regulating the position of candidates who were passed as qualified but not successful. He would move that application be made to the Directors-General for the desired information.

Dr. MCVAIL seconded the motion, which, after some remarks by Mr. Simon, Mr. Wheelhouse, Dr. Bruce, and Dr. H. Watson, was put and negatived.

A communication was received from the Lord President of the Privy Council enclosing an application from the Society of Apothecaries for a postponement of the "appointed day" mentioned in the Medical Act, and asking the opinion of the Council on the subject.

Dr. HAUGHTON moved that the matter be deferred till after the consideration of the motion by Mr. B. Carter for the appointment of assistant examiners to the Society of Apothecaries.

It was pointed out by Mr. Simon, Dr. Quain, Sir W. Gull, and others, that when the matter was mentioned at the last meeting of the Council it was understood that if the extension of time was required it should be allowed.

Dr. Haughton's motion was not seconded, and it fell to the ground. A motion for the required extension of time was then agreed to.

Mr. B. CARTER then moved: "That, in pursuance of the application made to the General Medical Council by the Society of Apothecaries of London, by letter dated April 12th, 1887, for the appointment of Messrs. W. J. Walsham, G. H. Makins, and Andrew Clark, to be assistant examiners to the Society, under the provisions of the Medical Act of 1886, the Council hereby appoint Messrs. Walsham, Makins, and Clark to be assistant examiners accordingly." He said that at the last meeting of the Council in February the decision on the question was postponed in order that a representation might be made on the part of the Council to the Royal College of Physicians and the Royal College of Surgeons, in the hope that the objections entertained by those bodies to a combination with the Society of Apothecaries might be overcome. That representation had been made, but unsuccessfully. During the interval the Society of Apothecaries had in some degree modified the terms of their application. They now asked for the appointment of the three named gentlemen as assistant examiners. The privileges of the Society of Apothecaries with regard to the licensing of medical practitioners dated originally from a charter conferred by King James I., but for the purposes of the discussion he would be content to trace them to various Acts of Parliament, some of them specially obtained by the Society and others affecting the Society in common with other medical bodies. The first and most important of the special Acts was that which came into operation in the year 1815. The College of Physicians absolutely refused to undertake the supervision and control of the medical education of the general practitioners, and the work was therefore committed to the Society of Apothecaries, which had ever since carried it on in what he believed was admitted to be an admirable manner. During the seventy years that had elapsed the licence had been conferred upon more than 22,000 practitioners, and the number of licentiates was at this moment about one-half of the whole medical practitioners of England. Of the thirteen gentlemen of English birth and English medical education sitting around that Council table, he believed seven held the licence of the Society of Apothecaries. The estimation in which the Society was held by Parliament was sufficiently shown by the fact that it was retained in the Act of 1886 as one of the bodies entitled to send a representative to the Council; but the Act, while requiring that no one should be admitted to the Register except as the result of an examination in medicine, surgery, and midwifery, did not give the Society any statutory right to confer a surgical qualification. It could not therefore grant to its licentiates the right of entrance to the Register unless it could combine with some other licensing body by which its deficiency in respect to surgery could be made good. It could hardly be expected that the Society of Apothecaries would be able to combine with any of the universities, because those universities already possessed the power of giving licences in medicine, surgery, and midwifery. The only bodies with which the Society could combine practically were the College of Physicians and the College of Surgeons, and some years ago such a combination was very carefully considered, and was at one time looked upon as being practically settled. Lately, however, the Royal Colleges had refused to carry out the arrangement which they once made. It was under these circumstances that the Society now appealed to the Council to carry out the intentions of the Act of Parliament. He held that the Council had a certain amount of discretion in the matter, but that discretion must be exercised in a just and reasonable manner, having due regard to the legal rights of the Society. Whatever their decision was, the Privy Council had absolute power to review, confirm, or reverse it, and he was strongly of opinion that the action of the Privy Council would be almost entirely guided in the matter by the grounds upon which the decision of the Council was arrived at. If it appeared that it rested upon grave, weighty reasons of public policy, there could be very little doubt that an adverse decision on the part of the

Digitized by Google

Council would be supported by the Privy Council; but if, on the other hand, they were influenced by sentiment, by corporation rivalries or jealousies, the Privy Council would reverse the decision. If any members of the Council were opposed to the granting the Society examiners, he respectfully invited them to formulate the reasons by which their views might be supported. His mind was perfectly clear on the question that if he were not the representative of the Society he should still vote in favour of the application. The only assertion that he had heard as to the mischief or evil that might arise from granting the assistant examiners was, first, that those examiners would enable the Society of Apothecaries to remain in competition with other licensing bodies, and that such competition would be likely to be disadvantageous. It could not surely be disadvantageous to the public, because the special function of the Council was to exercise a supervision over examinations, to see that they were adequate for the protection of the public, and not unduly severe in their claims on the medical student; and for the Council to say that the existence of one or more examining bodies would tend to lower the standard of examination was to admit at once their own inability to discharge the functions which the Act imposed upon them. His own feeling was that the action of competition would be precisely the reverse, and that nothing but good was likely to come from it. If there was room for useful work for both the bodies, they would survive and do the work; but if there was not room, the fittest only would survive; and if the time came for the Society of Apothecaries to be extinguished, it would extinguish itself by a process of natural decay, of which, however, he at present failed to see even the very earliest indications. The idea that the Society would be likely to use what had been called competition downwards was one which had appeared to him no gentleman was justified in gravely putting forward, because it was totally opposed to the whole past history of the Society. He could quote in defence of his position the professional authority of the Royal College of Physicians of London, which was so much impressed with the necessity or the desirableness of some competition in London that in the year 1861 or 1862 it established an organisation, and went out of its way to set up competition where none before existed, and by recent decisions the College had shown how thoroughly it adhered to what it had done. He asked the Council not to deprive the public of the benefits of that system of competition which the College of Physicians had made sacrifices to establish, and which even within the last week it had declared it would not abandon. The reason why three examiners had been named was because the Act stated that they should have the power to appoint on the application of the corporation, and it was doubtful, therefore, whether the Council would have any power to appoint either more or fewer examiners than those that were applied for. The gentlemen named were appointed examiners by the Society of Apothecaries in 1884; they were gentlemen of the highest surgical attainments and of great practical experience. The Society put forward their names without any shadow of hesitation as to their fitness for the work.

Mr. SIMON seconded the motion. He said he did not agree in the view that it was desirable to have competition among examining boards, but the Council was now in this dilemma that they must either have the two examining boards in London, or must disobey the intentions of the law. It was on that ground that he seconded the motion. The Act of Parliament was obligatory upon the Council unless they had strong and definite reasons to the contrary. They might refuse, but they could not do so unless they had some reason which was not before Parliament at the time of the passing of the Act. If Parliament had meant to extinguish the Society of Apothecaries, it would have done so itself. That proposal was before Parliament, but was withdrawn. Such a thing was never dreamed of in Parliament as to give power to the Council to extinguish a body with vested rights against whom no complaint had been levelled. If they had been at the present moment before the Privy Council with an accusation against the Apothecaries' Company for having unfitly discharged its duties, then without doubt they might refuse to entertain the application, and probably the Privy Council would support them. If there had been anything wrong in the examination, it was the duty of the Council to represent it to the Privy Council, but in the absence of any such representation the examination of the Apothecaries' Company was supposed to be as good as that of the University of Cambridge for all purposes of the law. If without any justification of that kind they would refuse to do what the Company asked them, they would place themselves in an extremely embarrassing position. What wrong had the Apothecaries' Society done that they should be at the mercy of the General Medical Council? The Council was not established on the Kilkenny cat principle, that some bodies should be able to eat up others. He extremely regretted the necessity of the vote, but he had not the least hesitation as to what was his duty, and therefore he seconded the motion.

Mr. TEALE said that the motion involved two separate things: first, the granting of examiners; and, secondly, the appointment of special persons.

Mr. CARTER said he was quite willing to alter the resolution so that it should read: "That in pursuance of the application made to the General Medical Council by the Society of Apothecaries of London, by letter dated April 12th, 1887, for the appointment of assistant examiners to the Society under the provisions of the Medical Act of 1886, the Council hereby consent to appoint assistant examiners accordingly."

Mr. TEALE regretted that it was necessary to establish a second competing Board of Examiners in London, but he agreed with Mr. Simon that they really had little option or discretion in the matter. If Parliament had intended that they should have the power to put an end to the Apothecaries' Society, Parliament would have done it itself. He therefore did not see how they could avoid coming to the conclusion to grant the request of the Society.

Permission was then given to Mr. Carter to amend his resolution, and Sir DYCE DUCKWORTH moved the adjournment of the debate.

The Council then adjourned.

WEDNESDAY, MAY 11TH.

MR. MARSHALL, PRESIDENT, IN THE CHAIR.

Adjourned Debate on Mr. Carter's Motion.

A proposal by Dr. AQUILLA SMITH, seconded by Mr. WHELHOUSE, to resolve the Council into a committee for the purpose of considering the application from the Apothecaries' Society was negatived, and the debate was then resumed.

Sir DYCE DUCKWORTH said that at the meeting of the Royal College of Physicians he was requested to state to the Council what the policy was that led the College to act as it had done. When the courteous letter from Sir Henry Acland was received it was accompanied by no fresh arguments, and as the whole question had been fully and maturely considered, both in committee and by the whole College, the first decision was reaffirmed *nem. con.* The College saw that it would receive no accession of strength by union with the Apothecaries' Society, that the examination established by the Conjoint Board would in no way be improved by the addition of such examiners as the Apothecaries' Society could send to it from its own body, and that such being the case no possible good could accrue to the public at large from conjunction with that body. If the Apothecaries' Society took part in conducting the examinations of the Conjoint Board, they would have to find their examiners from without, and they would cease to issue diplomas upon their own account, so that, in fact, they would be nothing more than a trading company in the City. One point that had been lost sight of was that the College of Physicians of London had power to give a complete qualification in medicine, surgery, and midwifery; so that it was really not incumbent upon the College to seek an alliance anywhere. For the general benefit, however, it was thought well that the College of Surgeons should be allied with it. At the time when there were negotiations for an alliance with the Apothecaries' Society all the universities of England negotiated too, but a very different state of things prevailed now. The action which the College took in 1861 in establishing a new order of licentiates had been of great benefit to the profession, and had improved the educational standard of general practitioners. If that was to be regarded as competition, it was at all events a competition upwards, but he was quite sure that it was in no way intended to compete with the examinations held every week in the Apothecaries' Hall. To those who knew the circumstances of the case it was simply ridiculous to talk of rivalry or jealousy. Speak-

Digitized by Google

ing simply as a member of the Council, and not as a representative of the College of Physicians, he considered that the Apothecaries were no longer wanted in this country. They had done their work well, but the need for them had passed away. That which they had done at one time was now much better done by the trained and examined members of the Pharmaceutical Society. The only reason why the pupils at the schools wanted to take a licence of the Apothecaries was because in some provincial hospitals, and in the bye-laws of various boards of guardians, it was required that, whatever diploma any candidate might possess, he must produce the licence of the Apothecaries' Society. It therefore happened that men who were eminently qualified and held the diploma of the College of Physicians and degrees of the universities, had, perforce, to go to Blackfriars and obtain the licence of the Society. The Apothecaries' system had been a great drawback to the profession of the general practitioner. It had been the means of spreading many mischievous ideas among the public, and the nonsense of homœopathy in this country was little more than a Nemesis following the apothecary. It was not for one moment to be doubted that the requirements of the two Royal Colleges were distinctly in excess of those of the Apothecaries' Society, and those who were interested in the levelling up of the profession must look askance at the reinstatement of the Apothecaries' Company. They had been threatened with an appeal to the Privy Council; but was the Medical Council to be muzzled and to be afraid to utter its opinions at a time like the present, and to defer to the opinions of a body of laymen who, however exalted and eminent, did not at present contain a single member of the medical profession, and who therefore were not qualified to form an opinion for themselves unguided by the Medical Council as to what was best for the highest interests of the profession. It was the duty of the Council to go forward boldly without any fear to do what it thought best and right for the profession and for the highest interests of the public.

Dr. STRUTHERS moved as an amendment: "With reference to the application made to the Council by the Society of Apothecaries of London, of date February 12th, 1887, received and entered in the Minutes of February 18th (p. 127), and to the further application by the Society to the Council, of date April 12th, 1887, that, in the opinion of the Council, it would be contrary to the interest of the public that the Society of Apothecaries should, through Section 5 of the Medical Act (1886), be enabled to grant a diploma qualifying for admission to the medical profession." At the last meeting of the Council he had proposed a resolution in favour of the Society of Apothecaries being admitted to the Conjoint Board, as he considered that the best way of getting rid of the difficulty which then existed was by process of absorption. The present proposal, however, was to revivify the Apothecaries' Society of London and put it in a position it had never before occupied—namely, that of being empowered to give a complete qualification. He opposed that proposal, feeling that the matter should be left with the Privy Council. His amendment was not designed to put an end to the Apothecaries' Society, which under the Act would in some respects come to an end in June, unless the Medical Council gave it a new life. But it had other functions to fulfil, and would still continue to supply medicines to the profession or to anybody else, and to prosecute quacks. Even if it ceased to do that, it could still confer the distinction of L.A.C. on those who chose to take it. In his opinion, it would be contrary to the interests of the public that the Society should be enabled to grant a diploma qualifying for admission to the medical profession. That the Apothecaries' Society should cease to be a licensing body was no new idea, for in the reports of the Select Committee in 1879-80 the opinion was sometimes expressed. By the Bill introduced by the Government of the day into Parliament in 1883, the Apothecaries' Society was only to have one representative on the Council, while the College of Physicians was to have three and the College of Surgeons three. When the Bill went into committee the Irish Apothecaries disappeared, and afterwards the London Apothecaries' Society was deleted from the Bill. Then, again, in the Bill of 1884 the Apothecaries' Society was left out. All those who were engaged on the Bill of 1886 knew very well that the Vice-President, Sir Lyon Playfair, was very anxious to pass what was passable, and to steer clear of all rocks ahead. He got quit of the difficulty of the Apothecaries very cleverly by putting it upon the Medical Council, and, if they did not settle it, leaving it to the Privy Council. If the application of the Apothecaries' Society were granted, the qualification which they gave must be an inferior one, and would lead to an inferior order of practitioners. At the last meeting of Council he was challenged by Mr. Carter when he spoke of the licentiates of the Society as apothecaries, but he found in the well-known Act of Parliament of 1815 there were constant allusions, not to a licence, but to a certificate to practise as an apothecary, and the examiners were required to examine a man "as to his fitness or qualification to act as an apothecary or assistant to an apothecary." If Mr. Carter's motion were agreed to, what kind of students would go to the examination? The men about whom there was something wrong might try for the certificate, but others would not. He did not think that any qualification should be attempted below the diploma of the Royal College of Surgeons. The profession was overstocked, and it was the duty of the Council to elevate it, and not to lower it—not to make apothecaries out of them, but to raise the members more and more. If the application were granted, the Council would perpetuate the system of supplying drugs. The competition of the universities was good, but the competition of the Apothecaries' Society would not be good. It was continually said that the Society ought not to be extinguished because it had done good work in the past. No doubt the Society put on an examination in medicine in 1815, but they obtained a monopoly along with it, and got the whole of the practice in England into their hands. An English apothecary was a thing that was not understood in Scotland or anywhere else in the world. The Apothecaries' Society used their power against the Scotch and against the Irish. The best educated man from Scotland or from Trinity College, Dublin, was regarded as an illegal practitioner in England. Formerly, if a Stokes or a Christison ordered a dose of rhubarb, he would have got a lawyer's letter, and have been mulcted in £20. No English Star Chamber ever used its powers more constantly than the Apothecaries' Society did.

Dr. QUAIN said Scotchmen were not allowed to cross the border to practise as apothecaries. The restriction did not apply to surgeons or physicians.

Dr. STRUTHERS said that the Apothecaries' Society became a trades union, giving the Englishmen the monopoly and keeping enterprising Scotchmen and Irishmen off the soil. An outburst of homœopathy took place in Edinburgh, but it was like the seed that fell on stony ground, and there was not now a pure homœopath in Scotland; but owing to the Apothecaries' Society homœopathy flourished in England, and, by teaching people to rely on nature and not trust so much to drugs, had done more good for the science of medicine than the Apothecaries' Society ever did. Mr. Carter had not referred to it, but outside a good deal had been said about the power of prosecuting quacks. On this matter, however, the report of the Medical Acts Commission said: "We consider it undesirable to attempt to prevent unregistered persons from practising, but at the same time we think that they should be prevented from representing themselves as being registered or assuming titles which would lead the public to believe that they are regular medical men." It was not creditable to any body of men at the present time to combine with another on the ground of the power to prosecute quacks. There were some things about the constitution of the English Apothecaries' Society which were not understood even in England. The Master of the Society, when giving evidence before the Medical Acts Commission in July, 1881, said that the Society touched none of the money that was paid for the examinations, the fees going into a fund entirely separate from the corporation, and being applied towards the expenses, the twelve examiners receiving £1000 a year between them, and the secretary of the Court of Examiners a salary of £200 a year. The Royal Colleges and universities had grand museums and magnificent libraries, but the Apothecaries' Society had no such things. It was an antiquated body, having its livery and its yeomanry, and using old phrases which dated back to the time when the surgeons were in alliance with the barbers. The Society was also a trading company, manufacturing and selling drugs and chemicals, not only by wholesale, but by retail, and dealing likewise in goods which it bought from other traders.

Dr. QUAIN said the Apothecaries' Hall was a distinct body from the Apothecaries' Society, and he protested against the

Digitized by Google

time of the Council being wasted upon hearing an argument which had no bearing upon the subject before them.

Dr. STRUTHERS caused some amusement by handing to the President a tincture, a powder, and a bottle of eau de Cologne which he had bought at the Apothecaries' Hall.

Sir WM. GULL seconded the motion.

Sir WALTER FOSTER said he was glad that Dr. Struthers had recalled the minds of the Council to the humbler branches of the profession, which were doing good and useful work. He had, however, endeavoured to appeal to sentiment not of the highest kind, and to revive recollections and grudges against the Apothecaries' Society. There was nothing disgraceful in shopkeeping when carried on in an honest spirit. They were now placed in a position of great gravity, being called upon to decide whether the competition between the licensing bodies of London should continue on those lines which the profession generally had condemned. If they refused to grant assistant examiners to the Apothecaries' Society it would appeal to the Privy Council, and it was generally thought that the Privy Council would concede them the right to continue by ordering the appointment of examiners. He did not think that the Council should have the power to destroy the Apothecaries' Society under the present condition of matters, unless they had a good reason of their own for it; but in that event they would not be acting in the interest of the public, but from a narrower professional ground. If they refused to allow the Apothecaries' Society to have examiners and were backed up by the Privy Council, they would have growing up in the profession a new kind of practitioner. A Bill was now before Parliament called the "Pharmacy Act Amendment Bill," which established for the Pharmaceutical Society a curriculum of which materia medica formed a part, which meant that pharmacists of the future would enter upon a course of study embracing part of the medical curriculum. The course of materia medica lectures would include a good deal more than a knowledge of the physical and chemical properties of drugs. It could not be denied that in hundreds and thousands of cases patients were prescribed for by chemists over the counter, and that practice would continue until they supplied properly qualified aid to the poor people. If the public were denied the opportunity of consulting those practitioners who were useful to them, they would soon ask for parliamentary powers authorising those practitioners to prescribe for them, and he consequently believed that, in the interests both of the public and of the profession, it would be wrong to remove the power from the Apothecaries' Society of giving qualifications for the practice of medicine. If the Apothecaries' Society failed to sustain its standard of proficiency the Council would have power to control the granting of its licences. He regretted that the matter had come to its present position, and he laid the blame on those Colleges which had refused their sanction to the proposal that had been made. For himself, he was willing to give his vote according to his convictions, which were that the Council should declare that the Society should have examiners, and, in the interest of the public, they should appoint examiners to assist the Apothecaries' Society in giving a qualifying diploma for entrance on the Medical Register.

Mr. WHEELHOUSE said he thought the apothecary was a necessity in England. He did not know how the poor in many isolated localities could obtain medicine if the general practitioner were not permitted to supply it. He had been very anxious that the Apothecaries' Society should be absorbed by the two Colleges, and that there should be one portal by which to enter the profession. If that could not be brought about, there should be some means by which competition could be kept up to a certain extent. He was himself a licentiate of the Apothecaries' Society, and he felt that he should be turning his back upon it if he were now to say that it ought not to have the powers which it sought. The Council would be able to keep up the standard of the Society's examinations, and he therefore hoped that the application would be granted.

Mr. MITCHELL BANKS said he believed that there was a strong desire on the part of the Council that an amalgamation should take place between the Society of Apothecaries and the other bodies, but those bodies had declined, and the Council ought not to have its judgment warped by that consideration. The fear of threatened consequences ought not to weigh on them for a moment. No valid argument had been brought forward to prove that the request made ought to be granted. It had been urged that it was necessary to have a low class of practitioners, but he did not believe that such a class was required. The question at issue was one of vested interests, but whatever respect they might have for such interests, they ought not to be allowed to override the public good.

Dr. LEISHMAN concurred in the interpretation given by Mr. Simon to the words "if they think fit," and said that he was able to vote for Mr. Carter's resolution, which left it open to the Council to consider what number of examiners should be appointed. He had no sympathy with the Society of Apothecaries, but he was bound to recognise its legal claims.

Dr. HAUGHTON said that he was now a complete convert to Mr. Carter's proposal, for which he intended to vote.

Mr. SIMON said that the question of the fitness of the Society of Apothecaries had been decided by Parliament, and it was not for the Council to attempt to override that decision. The Council had a legal duty to fulfil towards the Apothecaries' Society, and if they did not do it the Privy Council would. If Dr. Struthers' amendment were defeated, as he hoped it would be, he believed that in two years there would be a conjoint board in London which would include the Apothecaries' Society.

Dr. DUNCAN said he could not accept the law as laid down by Mr. Simon. When the Act used the words "if they think fit," it did not mean nonsense, but it meant what it said. The prophecy of a one-portal system in two years he considered a ridiculous one, and he believed that if the profession were polled the general feeling would be expressed that the system was the abomination of abominations. He had great respect for the Apothecaries' Society, and regretted to have to vote for a proposal that might lead to its extinction. Mr. Simon's statement about the intention of the Legislature in passing the Act was mere idle talk. That intention could only be gathered from the Bill itself. He had learned from the highest authorities in the College of Physicians with which he was connected that the intention was that the Society of Apothecaries should be extinguished if the Medical Council thought fit.

Dr. BRUCE said that he thought Mr. Simon's argument in reference to the words in Clause 14 was unanswerable. Although he had at one time been an advocate for the one-portal system, he believed that if that system were carried out it would lead to a dull uniformity, and that the best thing was free open competition. If it had been the intention of the College of Physicians when the Act was being passed to extinguish the Society of Apothecaries, that view ought to have been frankly declared.

The debate was adjourned.

(*For continuation of Report see p. 1003.*)

JERUSALEM HOSPITAL FOR JEWS.

THE English Hospital for Jews in Jerusalem, in connexion with the London Jews' Society, has been established for over forty years for the gratuitous relief of the sick. It was the first hospital founded in Jerusalem, though many similar institutions have been established since then by the different nationalities. The work of the institution lies amongst the Jews, of whom there are about 25,000 now in Jerusalem; but Arabs are also occasionally seen. The hospital has twenty-six beds. There appears to be some difficulty in respect of the nursing, for which the managers of the charity have to depend entirely on such aid as can be procured in the place. Mr. Percy D'Erf Wheeler, M.R.C.S., L.R.C.P. Lond., is both physician and surgeon, and he is assisted by a proselyte educated for the medical profession in Hungary. A dispensary is connected with the hospital, and all the drugs and instruments are from London houses. Every kind of case is admitted, and patients arrive from Persia, Armenia, Circassia, Tunis, &c., many of them suffering from diseases of the eyes. They say they prefer coming to an English hospital. The sanitary condition of the city is stated to be deplorable, and the services of the medical staff of the hospital are found to be necessary not only in treating disease, but in directing the minds of the people to the paramount importance of cleanliness and sanitation. Malarial fever heads the list of diseases for which relief is sought. During the year 1886 the in-patients numbered 6052, and the total consultations amounted to 37,018—a figure which speaks eloquently of the good work done in connexion with the institution.

THE LANCET.

LONDON: SATURDAY, MAY 14, 1887.

THAT there is something radically wrong in the present state of medical education is a proposition which at the first blush seems almost preposterous. That, with all our boasted improvements in the art of teaching, with a large body of teachers, never more zealous and devoted than at present, the results of the Final Examinations should be so deplorable as they confessedly are, surely evinces an error in method somewhere. Dr. GLOVER, it may be remembered, urged the point as evidence of a lack of practical knowledge, and thought that a return more or less to the old apprenticeship system would prove a remedy. That in 1885, according to the official returns, no fewer than 56 per cent. of the candidates were rejected at the Final Examinations of the Edinburgh Colleges, 48·2 per cent. at the Royal University of Ireland, and 44·1 per cent. at the College of Surgeons of England, are results which, to use Dr. GLOVER'S words, may well be styled "appalling" and "very painful." For it must be remembered that the candidates are all men who have completed the prescribed curriculum under all the advantages now offered for a complete training, and it is shocking to find so poor a result after so much labour. It is hardly possible to attribute this solely to the causes assigned by Dr. GLOVER, and it may be worth while to inquire whether there may not be other and less remote reasons for the high percentage of rejections.

The experience of the last few weeks of the examination held by the College of Surgeons supplies an answer to this inquiry, and clearly demonstrates that a large share must be laid at the door of the examination itself. For the number of rejections among the candidates at this Final Surgical Examination has been considerably in excess even of that given for the year 1885. There must be something wrong in system and in method to permit of such a large percentage of rejections, and we call upon the London teachers, who are all interested in this question, to spare no effort in determining the real cause of this regrettable state of things.

Much praise has been bestowed upon the examinations of the College of Surgeons for their stringency; but an equal amount of blame is due for their uncertainty. The personal equation plays a prominent part, for owing to the system that prevails, whereby the results of the written and those of the oral examinations are kept apart, and the comparatively high value set upon the few minutes' oral examination, it is obvious that the chances of success or failure must lie largely in the demeanour of the candidate and in the fitness of the examiner for his work. The rough-and-ready methods of old days have their survival in the present, and the student, who knows often as well as his teachers, and certainly better than his examiners, the standard of his fellows' knowledge, comes to regard the passing of an examination where the strong sometimes fail and the weak succeed as a game of chance, and trusts that he may have the luck to meet with a leniency which he may not merit. It is this uncertainty, due almost entirely to deficiency in the "art of examining," that is doing a great deal to bring into contempt examinations which we have perhaps been too apt to praise for their practical and searching character. That this is no new discovery may be gathered from the outspoken evidence of Mr. CHRISTOPHER HEATH, given before the Medical Acts Commission. Speaking of the examinations at the College of Surgeons, he says:—

"4065. One man may be lucky. He may go to a man at one table who is an easy examiner, and he will get through; and his friend, who has got a more difficult examiner at a table the other side of the room, does not get through. I do not know, human nature being as it is, how it is to be avoided."

Again, a little later Mr. HEATH makes the following remarkable admissions:—

"4069. (Prof. Turner.) I have heard complaints as to the examination of the Royal College of Surgeons of England, as to its being so uncertain an examination. Do you think there is any foundation for such a complaint?—It is uncertain.

"4070. What you have said with regard to the different standards at the different tables bears out the statement of its uncertainty?—Quite so.

"4071. So that I suppose you would not put forward the examination of the College of Surgeons of England as a model examination?—No, I think it might be modified with advantage in some way.

"4072. And perhaps in some respects in the way of diminished stringency and of less uncertainty?—Yes."

Further comment is needless. The statements of 1881 hold good for 1887; and we maintain that the credit of the College of Surgeons (ay, and the College of Physicians, too, since it has become a partner in the Examining Board) is at stake, for its reputation depends on the maintenance of a just uniformity in the performance of its duties as a qualifying body.

IN continuation of our remarks on the report of the Manchester Medico-Ethical Association on the question of the defects in the constitution of the Coroner's Court, we proceed to deal with the most important part of the whole document. We allude to paragraph 1 at the bottom of page 16: "The examination of the body upon which an inquest is to be held should be made by a medical man specially skilled in such matters, who should be designated the Public Pathologist, and that for every coroner's district there should be one or more such pathologists appointed to conduct the examination of the body previous to the inquest." The second paragraph advises that the appointment of the pathologist should be made by the Crown. This, it may be remarked, is quite impracticable; the pathologist should be not an officer appointed by the Crown, but an expert witness called by the coroner. The third paragraph provides for the calling in of further scientific experts for analysis, &c. The fourth paragraph is very important, and is this: "The duties of the public pathologist should not preclude the medical attendant in the case from giving evidence as a skilled witness where necessary." At present coroners are compelled by the Medical Witnesses Act to summon the medical attendant in the last illness, or, failing this, "any legally qualified practitioner in actual practice in or near the place where the death happened." The majority of

Digitized by Google

jurymen at such inquest may also call for the evidence of such other medical witnesses as they may desire. From this it will be seen that the present law is sufficiently elastic to provide the requisite evidence without so sweeping a change as would be involved by the appointment of public pathologists by the Crown. The employment of the medical attendant or local practitioners by the coroner has been the subject of ceaseless attacks, and it is somewhat lamentable to read in the report under consideration that the medical attendant is not to be precluded from giving evidence as a skilled witness when necessary! A large proportion of the cases forming the subjects of inquests are those of sudden illness, poisoning, and violence of all kinds, in which the assistance of the nearest practitioner must be sought. Should death occur and an inquest follow, he is the only witness who can give evidence as to symptoms, appearances, &c., and his evidence must, as a matter of course, be necessary. Moreover, should a post-mortem examination be requisite, and the medical attendant be willing and desirous to undertake it, why should he be requested to stand aside and give place to a pathologist? THE LANCET has always appeared as the champion of the rights of general practitioners, and in continuance of this course we must protest against the proposed shutting out of the medical attendant as utterly unwarrantable. For not only is it, as we have seen, unworkable so far as the giving of evidence is involved, but it wholly ignores the fact shown by past history, that the average general practitioner in town and country has frequently shown himself to be as competent to make a post-mortem examination and to face with credit to himself a severe cross-examination in the witness-box, as to attend a difficult midwifery case, to set a fracture, or to perform any of the other numerous and multifarious duties which fall to a general practitioner's lot. In 1845 occurred the case known as the TAWELL murder, in which the deceased woman, SARAH HART, died from poisoning by hydrocyanic acid. The three local practitioners of the rural district where the death took place (Messrs. CHAMPNEYS, PICKERING, and NORBLAD) conducted the necropsy; and those who will refer to THE LANCET of that year will find that their report leaves little to be desired. Moreover, so carefully were the stomach and its contents removed, handled, and forwarded for analysis, that, though the nature of the poison was not known, the analyst (COOPER) was enabled to distil from the contents of the stomach one grain of pure anhydrous hydrocyanic acid. Could a skilled pathologist have done better? Again, when the Rugeley poisonings occurred in 1855, the late Dr. MONCKTON, then of Rugeley (subsequently of Maidstone), was entrusted with the examination of the exhumed bodies of ANN and WALTER PALMER. He published minutes of these in THE LANCET of 1856, and they may be profitably referred to now as models of how to proceed in future inquiries of the kind. And numbers of similar cases might be given. What is required is, not to shut out the medical attendants or local practitioners, but to encourage amongst them the careful and practical study of forensic medicine.

But though anxious to guard the interests of the general practitioner, it is not to be inferred that the present mode of conducting necropsies for coroners is in our opinion satisfactory. Very far from it. In every case involving a criminal charge against a suspected person there ought to be a second medical examiner without waiting for this to be asked for by the coroner's jury. It is obviously undesirable that all the important evidence afforded by a post-mortem examination should be the solitary possession of one medical witness, who might subsequently be unable to attend the trial from illness or even death. This has not infrequently happened, and the prisoner has thus been deprived of the advantage which might have followed a cross-examination of the only medical witness. On this account alone the presence of a second medical witness is most desirable, and this being admitted, it follows naturally that he should be one well experienced in necropsies and thoroughly acquainted with all the appearances of the internal organs, both morbid and healthy. The evidence of a skilled pathologist is very valuable, but it is also desirable that the second examiner should possess a competent knowledge of legal medicine. In a leading article published in THE LANCET of March 7th, 1885, it was remarked that the position of forensic medicine in this country was not what it ought to be. It has not kept pace with physic, surgery, ophthalmic surgery, obstetrics, or the other branches of medical study. The cause is not far to seek. Though for many years past attendance on one course of lectures on medical jurisprudence and toxicology has been compulsory upon every medical student, the lectures, with few exceptions, have not been of a nature to render the subject attractive; in most provincial and some metropolitan schools the lectureship has been too often regarded as a mere stepping-stone to some other more lucrative chair —a condition of things disastrous both to lecturer and students. Those who have attended the lectures of the late Professor SWAYNE TAYLOR, his successor Dr. THOMAS STEVENSON, Dr. TIDY, Dr. OGSTON of Aberdeen, or Dr. LITTLEJOHN of Edinburgh, will know how deeply interesting and practically useful this course of lectures can be made. In future care should be taken that the lecturer on forensic medicine in every medical school should be able to teach his subject practically as well as theoretically; and, as a means towards securing this, he should be an experienced pathologist. His aid should be sought by coroners and medical practitioners in all necropsies of a medico-legal character, the medical attendant and he making the examination jointly. By this simple arrangement, which could be brought about quietly, voluntarily, and without any alteration of the law, the rights of general practitioners would be respected, the latter would be afforded valuable help at a time when it is much needed, a considerable saving would be effected of scientific material now wasted, and a great impetus would be given to the better cultivation of forensic medicine. The various classes of this branch of medical study commenced this month, and we would call the serious attention both of teachers and students to recent trials, especially those of the Oldham poisoning case and the Hoxton murder. The first shows how important it is for every medical practitioner to have his wits always ready for any emergency, even in his most routine duties. Poisoners generally work insidiously, and take full advantage of every circumstance likely to remove suspicion from them. The Hoxton murder emphasises the excellent advice given by Lord DEAS at a trial in Aberdeen in

Digitized by Google

1855: "A medical man, when he sees a dead body, should notice everything." The same case also shows the importance of making careful notes of all the post-mortem appearances for the purpose of refreshing the memory at the trial. What made the lectures of the eminent medical jurists to whom we have referred so valuable and interesting was the number of cases which they were able to give from their own experience. It is this which made CASPAR'S work so valuable a book of reference. But London, Edinburgh, and Berlin do not possess a monopoly of all that is valuable in forensic medicine. Every coroner's district may furnish its quota, and it is the duty of all practitioners throughout the kingdom, while standing up for their undoubted rights as afforded them by the Medical Witnesses Acts, to give every assistance towards the practical study and cultivation of forensic medicine and toxicology.

OF all the means which medical men possess for the saving of human life there is none so potent for good as vaccination. The amount of sickness and death which is prevented by this operation is almost incalculable, yet it is no exaggeration to state that there are few subjects of which the teaching is so lamentably neglected in our medical schools. The fact that vaccination is regarded as a trifling operation which can be performed by anyone leads to large numbers of men who engage in practice having the most elementary knowledge of its nature. The result is that vaccination is considered by many to be the mere inoculation of vaccine lymph, without any relation to the effects which will be produced in protecting the patient against so fatal and disfiguring a malady as small-pox. There is no question that comparatively few realise the full importance of the duty they are undertaking when they vaccinate, or understand that upon their method of operation depends the probability of their patient being protected for a long or short time against attack or even death from this disease.

A recent discussion by the Society of Medical Officers of Health was the occasion of statements being made which show that the want of knowledge of parents is often allowed to influence the action of the operator to the distinct detriment of the child, and, as a result, vaccination is credited with failure to sufficiently protect against small-pox, simply because it has been inefficiently performed. So far as relates to public vaccination, the Local Government Board have endeavoured to raise its standard, and have, by the issue of instructions for vaccinators under contract, pointed out the proper method of the performance of the operation and the means of guarding against all risk of injury. It would be well if the profession would understand that the instructions are not less applicable to private than to public vaccinators, and that it is their duty to protect as completely as possible their patients against attack by small-pox. These instructions state definitely that at least four separate good-sized vesicles, or groups of vesicles, should be made, so that the total area of vesiculation on the same day of the week following the vaccination should be not less than half a square inch. This recommendation is based upon an experience of many years, and upon the evidence which every small-pox hospital affords, that the severity of attack by small-pox subsequent to vaccination is inversely proportionate to the number of cicatrices. It should therefore be clearly understood that any medical man vaccinating less efficiently than is here indicated is guilty of an act of injustice to the individual who has placed himself under his care for the purpose of being protected against small-pox. It cannot be pleaded that vaccination of this sort exposes the patient to greater risk than a less complete performance, and everyone who neglects to comply to the fullest extent with this requirement incurs a serious responsibility, which it is impossible to evade.

There are reasons for the postponement of vaccination; there are none which can justify its ill-performance. Of the reasons for postponement may be mentioned those which are specifically stated in the instructions. The patient should, at the time of vaccination, be in good health, and, if an infant, should not be in any febrile state, or suffer from any irritation of the bowels or any unhealthy state of the skin, nor should he have been recently exposed to the infection of measles or scarlet fever, or any chance of risk from erysipelas which may happen to prevail in or about the place of residence. There is only one circumstance under which this advice can be set aside—that is, where there is definite exposure to small-pox, when the risk of death from this disease will justify the infraction of these rules.

As to the subjects from which lymph may be taken, the instructions are equally specific. They must essentially be healthy children, of whom preferably the family history is known, and they must be absolutely free from skin disease, from any sort of sore at or about the anus, or other sign of hereditary syphilis. Lymph must only be taken from children vaccinated for the first time, and never from cases of revaccination; and, again, only perfect vesicles without conspicuous areola should be permitted to supply it, and lymph contaminated with blood or by running over the skin must be rejected, as well as that which is thin and watery or not clear and transparent.

The precautions against septic injury are based upon the maintenance of absolute cleanliness of instruments, of subsequent dressings, and upon, as already said, freedom from exposure to septic disease. The need for the instructions as to cleanliness has unfortunately been strongly emphasised by accidents due to neglect. Lancets, it has to be remembered, are not the only instruments which are capable of inflicting injury in this manner. Our readers will not have forgotten the calamity at Norwich which led to the instruction that ivory points and capillary tubes should not be used a second time; we are induced to dwell especially upon this recommendation for the reason that the Local Government Board have just issued a report by Dr. AIRY on a death from erysipelatous disease after vaccination, the operator having omitted to exercise the precaution which is here enjoined.

By the loyal adoption of these recommendations, the few accidents which now occur from vaccination would be materially reduced in number, and an operation which saves yearly thousands of lives would meet with less opposition from those whose very existence is often dependent upon its performance. It may be hoped that in the future the General Medical Council may recognise the necessity for students being better taught in a branch

Digitized by Google

of practice in which they will all more or less have to engage; but the absence of this teaching, which we lament, makes it the more necessary that the instructions of the Local Government Board should be carefully studied by private as well as public vaccinators.

WE had hoped that the question of the military status of the medical officers of the army would have been settled by the assurances given by the Secretary of State for War and the alteration in the Royal Warrant which he intimated. But this, it would appear, is not to be the case. An outcry has been raised for the grant of *honorary* rank to the medical officers, in the same manner as it is now given to the officers of other departments of the army. We cannot but think that this is a retrograde step. The wording of the Warrant as proposed to be now issued appears to us, as we have already pointed out (see THE LANCET for April 23rd, p. 836), to carry with it *substantive* military rank, for we are unable to conceive of any more clear definition of substantive rank to a medical officer than that his position and powers are the same as those of the corresponding grade in the combatant ranks, within the specified limits which clearly mark out their several and respective spheres of action. And for this substantive rank it is now proposed to make a fight for *honorary* rank. It is certainly rather amusing to find those who profess to be indignant at being placed in the same category with the officers whose duty is the supply and pay of the troops claiming to be classed with these very officers by having honorary rank given them. It is asserted that the abolition of the term "relative rank" has left only two descriptions of rank in the army, substantive and honorary. Surely of these two substantive is the more to be desired, and if Her Majesty decrees that medical officers shall rank *as* the corresponding grades of military officers, this manifestly constitutes substantive rank. The movement, then, would appear to involve a protest against the more desirable rank, with a view to obtain in lieu of it that which will associate the medical officers with those departments whose duties are such as not to expose them to the same dangers on field service as the so-called combatant and as the medical officers. But we are afraid that below the surface there is a desire on the part of a section of the Department to have military instead of professional titles. In our opinion the latter are the more honourable of the two, and when, as it is now proposed, all the privileges of substantive military rank, so far as they can be enjoyed by medical officers, are conferred on them, it would be indeed "an undignified and false position" to lead the public to believe that "they need the support of purely military titles, indicative of and appertaining to a profession to which they do not rightfully belong." If our view be correct—and we firmly believe it to be so—that the Royal Warrant confers substantive rank, the medical officers will be in a much better position than if they were to obtain honorary rank.

IN his opening address the President of the General Medical Council placed clearly before its members the steps which had been taken since the last session to prevent the continued existence of separate licensing bodies in the metropolis. Sir HENRY ACLAND'S action could not be criticised by those who are most jealous of the dignity of the Council, and the profession will remember with gratitude the part he has played in proceedings which have unfortunately been unsuccessful in their result. The satisfaction will always remain that the Council have used their best efforts to carry out the intention of the Act of 1886, and the responsibility of failure must henceforth rest alone upon the Royal Colleges of Physicians and Surgeons.

The arguments in favour of amalgamation have so frequently been discussed in these columns that it is unnecessary to repeat them; it is sufficient to state that the position of the Apothecaries' Society and their right to continued existence were represented by Mr. BRUDENELL CARTER, who again urged the Council to consent to the application of the Society of Apothecaries of London for the appointment of assistant examiners to the Society under the provisions of the Medical Act of 1886.

Sir DYCE DUCKWORTH has certainly failed to make clear the grounds upon which the Royal College of Physicians have refused to accept the advice of the Medical Council. The College, he argued, had power to give a complete qualification in Medicine, Surgery, and Midwifery; it could receive no accession of strength by union with the Apothecaries' Society and, such being the case, no possible good could accrue to the public at large from conjunction with that body. Notwithstanding the possession of this power to give a complete qualification, the College of Physicians have thought it well to combine with the College of Surgeons "for the general benefit." If we have comprehended rightly the intention of the Act of last year, the general benefit was its ostensible aim, and it is difficult to understand that regard for the public interests should, under these circumstances, have indicated the desirability of combination with one body and not with the other. The question has, however, passed this stage, and it only remains for the Council to decide whether they will grant or refuse the appeal of the Apothecaries' Society.

In taking farewell of the Council, Sir HENRY ACLAND commended to their consideration the address which it was proposed should be submitted to the QUEEN on the conclusion of the fiftieth year of her reign. The address properly refers to the great advance which has been made in the health conditions of the people, the appointment of a public health administration, and the good results which have accrued therefrom, as well as the progress which has been made in every department of rational medicine; and it bears witness to the support which the QUEEN has always given to subjects which thus intimately promote the happiness of those over whom she rules. In this last act of his official life, the President will have the warm approval of every member of the profession.

The appointment of Mr. JOHN MARSHALL to the presidential chair was unanimously agreed to by the Council, and will give general satisfaction. It is right that the body engaged in the control of medical education should be presided over by a representative of the highest scientific attainments, and no one is better fitted to undertake the responsible duties of the office than the newly-elected President. The admirable service which Mr. MARSHALL has already rendered to the Council directly indicated him as the successor to Sir HENRY ACLAND, and gives the best promise that its increasing powers will be utilized for the continued advancement of the profession.

Annotations.

"Ne quid nimis."

QUALIFICATIONS UNDER THE NEW ACT.

THE new Medical Act recites:—"A qualifying examination shall be an examination in medicine, surgery, and midwifery held for the purpose of granting a diploma or diplomas, conferring the right of registration under the Medical Acts, by any of the following bodies—that is to say: (*a*) Any university in the United Kingdom or any medical corporation, legally qualified at the passing of this Act to grant such diploma or diplomas in respect of medicine and surgery; or (*b*) any combination of two or more medical corporations in the same part of the United Kingdom who may agree to hold a joint examination in medicine, surgery, and midwifery, and of whom one at least is capable of granting such diploma as aforesaid in respect of medicine, and one at least is capable of granting such diploma in respect of surgery; or (*c*) any combination of any such university as aforesaid with any other such university or universities, or of any such university or universities with a medical corporation or corporations, the bodies forming such combination being in the same part of the United Kingdom." With regard to the above-named clause, we understand that the authorities of the University of London consider that the M.B. degree will be registrable apart from the B.S., because the examination for the former includes the three subjects required by the Act. The wording of the clause, however, seems to be very ambiguous and difficult of interpretation; and it is not easy to see how far "qualifying examinations" will entitle "the following bodies" to place upon the Medical Register such higher diplomas and degrees as the F.R.C.S., M.R.C.P., B.S., M.S., and M.D., which, although nearly invariably granted after "qualifying examinations" have been passed, do not in themselves fulfil the requirements of the Act. It certainly seems not improbable that this unfortunate piece of medical legislation may afford more benefit to the legal than to our own profession. We trust the Medical Council will take steps to inform the profession what is really the true status, as far as registration is concerned, of the various degrees and diplomas. They are, it is true, an executive body, but they can hardly carry out their duties without knowing what is definitely required by the Act. The L.R.C.P. Lond., although single, is a complete qualification under the Act, but, owing to the combination of the Colleges of Physicians and Surgeons, is only applicable to persons commencing medical studies before October, 1884. Colonial M.B.'s requiring a registrable English surgical qualification must now take the L.R.C.P. conjointly with the M.R.C.S.

THE NEW CHARTER OF THE ROYAL COLLEGE OF SURGEONS.

WE may not unfairly claim to have secured at least one crumb of concession from the magnates in Lincoln's-inn, who rule so absolutely and so despotically in all matters concerning the College of Surgeons. The concession, it is true, concerns a matter of comparatively trifling importance. As we pointed out in a recent article, notwithstanding repeated and emphatic expressions of opinion by large numbers of Fellows and of Members, the Council persists in its determination to apply for a new Charter which ignores the Members of the College and leaves them unrepresented on the Council, although they form nearly nine-tenths of the entire constituency and contribute very largely to the College funds. The concession we allude to is this: The Council have decided that an official abstract of the petition for the new Charter shall be prepared and issued to any Fellow or Member applying for the same. They do not think it expedient to have another general meeting to discuss the prepared draft of the Charter, as the subjects to which it relates have already been submitted to previous meetings of the Fellows and Members. We presume that an "official abstract of the petition" will include the new parts of the proposed Charter; for, after all, that is what is really wanted, and that is what the Association of Fellows asked for in the resolutions which they addressed to the Council some time last month. The Association of Fellows at the same time ordered a letter to be sent to the Lord President of the Council begging that the proposed Charter about to be applied for by the College be not approved until the Association of Fellows has had an opportunity, by means of a deputation, of stating and explaining its defects. The Association of Members would do well to address a similar request to the Lord President. It is hardly necessary for us to urge on them also the presentation of their petition. When this is done they must be careful in the selection of speakers. It would be invidious to name some in preference to others; nevertheless, it should not be a difficult task to select the very best men for the purpose, if the memory is allowed to go back to the general meetings of the Fellows and Members that have been held at the College. We shall be very much mistaken and disappointed in our estimate of the Lord President of the Council if the representations of two such deputations—the one representing the Fellows, the other the Members of the College of Surgeons—are entirely without effect. In other words, we much doubt whether the Lord President will sanction a new Charter, which is promoted only, and not even unanimously, by the present Council, and to which a very large proportion of the rest of the body corporate is strenuously opposed. But we shall soon see. We cannot but regret this continued antagonism of the Council to the natural aspiration of the Fellows and Members. So long as it continues, energy and thought are being wasted, of which the corporation has need for purposes of its development. A house divided against itself cannot stand: the College of Surgeons will prove no exception to the rule. The feeling of the Fellows and Members is so widespread, so well founded, and so reasonable, that sooner or later they will succeed in carrying their points, provided only they do not weary of the struggle, but continue to fight in a legitimate manner until their demands are satisfied.

METASTASIS IN ERYSIPELAS.

AN interesting contribution has been lately made to the pathology of erysipelas by Dr. von Noorden (Abstr. by Weichselbaum, *Centralblatt f. Bacteriologie*, No. 18). It is based upon a fatal case of facial erysipelas, in which there was also suppuration in the sheaths of the extensor tendons of the right hand, parenchymatous nephritis, acute oöphoritis of the left side, and acute swelling of the spleen. It was concluded that this was an instance of secondary or metastatic infection of erysipelas. The blood in the cardiac cavities and the pus from the inflamed hand were found to contain large quantities of a streptococcus, which neither microscopically nor by cultivations could be distinguished from S. erysipelatis or from S. pyogenes. Inoculations of the cultures obtained from the blood were made in the ear of rabbits. In three instances only redness, without swelling or suppuration, occurred; in one of these cases only isolated chains of cocci were found in the lymphatics of the ear. In a fourth rabbit there was no local effect, but death followed in two days, and the blood was found to contain numerous streptococci; whilst in the fifth rabbit redness of the ear appeared on the sixth day, and numerous chains of cocci were detected in the lymphatics of the amputated ear;

Digitized by Google

yet on the twelfth day, when the animal died, no cocci were found in the blood. These variable results led Noorden to conclude that animal experimentation was an insufficient test of the species of streptococcus; and further that, contrary to general opinion, the erysipelas-coccus may under certain conditions gain entrance into the blood. This infection may, he thinks, explain the occasional occurrence of secondary pneumonia; but Weichselbaum states that in such cases the pneumonia is not due to the erysipelas-coccus, but to the diplococcus pneumoniæ, and that it is incorrect to speak of an erysipelatous pneumonia. The case related by Noorden was probably one of pyæmia, due to infection by the streptococcus pyogenes.

MEDICAL JURISPRUDENCE AT KIMBERLEY.

ON Nov. 21st, 1886, a man named Grattan was found dead. He had been attended some time previously by a medical man, who diagnosed "mitral disease of the heart." The brother of the medical man, also a doctor, was called to see the deceased after he had been dead "apparently for some hours." Finding nothing in the history of the case or in the surroundings of the body to cause him to suspect poisoning, he, with the permission of a relative of the deceased, opened the abdomen and examined the stomach, and, feeling satisfied with the negative evidence it afforded, certified that death arose from natural causes. As in all hot climates it is desirable for interment to take place without unnecessary delay, Grattan was buried on the day following his death. According to Dr. Croghan, Mr. Robinson (Grattan's relative before referred to) informed the police of the death within a quarter of an hour of the finding of the body. Subsequently, on information received, the assistant resident magistrate ordered an exhumation, and a second and more complete necropsy was made by Drs. Harris Grimmer, and Cumming. These gentlemen failed to detect heart disease in any form, but discovered old tubercular affection of one lung. Suspecting that poison had been taken or administered, they placed portions of the body in spirits of wine, with a view to preserving them for future analysis. In a letter to the Kimberley *Daily Independent*, Dr. Croghan complains that a preservative was added to the parts to be analysed, but on what grounds we fail to see, as not only was the measure a justifiable one, but it was pursuant to official instruction. The analyst at Cape Town detected prussic acid in the body. This seems a remarkable fact, for Dr. Croghan states that there was no odour of that poison in the room in which deceased was found, either before or after the body was opened. Had prussic acid caused the death—and in the face of the report of the official analyst we are not in a position to dispute it,—undoubtedly it ought to have been discovered at the first necropsy, either by the smell or by the glass plate test, which might have been then and there applied. We have known cases in which this test has succeeded when applied to blood taken from the heart two or three days after death. We have many times expressed the opinion that whenever a person is found dead, the coroner or his representative should be informed of the fact. In this way the medical man frees himself from all responsibility, and shifts it on to the person designed by the law to bear it. It was, of course, injudicious on Dr. Croghan's part to open the body without an official order, but having done so why did he not complete the examination, or at least satisfy himself of the existence of the heart disease that his brother had discovered during life? Negative evidence as to the cause of death is all very well as far as it goes, but it should not be accepted where there is the possibility of getting positive testimony. A wound was found on the wrist of the deceased, which Dr. Croghan asserts was caused by the bite of a dog, but which Dr. Harris says was inflicted by a bullet. Surely such a discrepancy is discreditable to the cause of surgery and of medical jurisprudence. A skilled observer could not fail to settle the point with certainty. There are other matters in this controversy which are rather of personal than of public interest, and therefore we decline to discuss them; but we may say that Dr. Croghan received scant courtesy when he was not requested to attend the official necropsy or informed of the time and place of its performance.

PRESENTATION DAY AT THE UNIVERSITY OF LONDON.

THE most interesting part of Lord Granville's speech on Wednesday last referred to the new scheme which is now ripe for consultation between the Senate and Convocation, and which will be laid before the latter body at an early special meeting. We have already given an outline of these changes, the chief effect of which will bring into the University representatives of associated colleges and of faculties as constituent elements. The maintenance of the high character of the University degrees and the Imperial nature of its work were strongly insisted upon by the Chancellor, his remarks being received with much applause by those present. It is to be observed that Lord Granville failed to refer to the real difficulty before the University. The time of the authorities is already so occupied with the numerous examinations at home and abroad, and the machinery of the University is so entirely devoted to this object, that a suitable constitution for a local teaching university cannot be framed, such as is wanted in London, as well as an Imperial examining board. It must surely be seen that the functions of the two bodies are quite different, and that they require separate and distinct organisations. The proposed scheme only touches the fringe of the great educational question in London which so urgently presses for a full and proper solution.

VIVISECTION IN 1886.

FROM the Home Office report, just issued, it appears that the experiments on living animals made last year under the provisions of the Cruelty to Animals Act numbered 1035. The total number of persons holding licences is sixty-four (forty-eight in England and sixteen in Scotland), and of these fifty-four have performed such operations in twenty-one separate buildings, of which eight are in London, eight in the provinces, and five in Scotland. Notwithstanding that these experiments come under the term "vivisection," as commonly used, a comparatively small proportion only were attended with pain to the animals experimented upon. In 458 cases the use of anæsthetics was dispensed with, on the ground chiefly that, the operation consisting merely in the slight puncturing necessary for inoculation, more distress and annoyance would be occasioned to the subject of the experiment by the administration of a narcotic than by the operation itself. Of the remainder, 213 cases were subject to the condition that the animal should be killed before recovering consciousness, in which cases, therefore, no pain at all was inflicted; while forty are reported as being painful in character. Even in these instances, however, the amount of pain inflicted was generally but small. Upon the whole, the official record warrants the belief that the demands of science have within the past year been reconciled with the infliction of a very small total of pain and inconvenience upon its victims. When our business and our sport come to be conducted with equal consideration for the brute interests involved, we shall be able to congratulate ourselves on having deserved well indeed of the lower creation. One passage in Mr. Erichsen's report suggests a doubt whether the Home Office is wise in the latest addition to its code of

Digitized by Google

vivisection rules. "It has been decided," we read, "that in future, if after the main result of the experiment has been attained pain be occasioned, the animal must be killed under the influence of an anæsthetic." Surely this is a most ill-judged regulation. If all that remains is to kill the animal, the most expeditious must usually be the most merciful method of procedure. To prolong a needless agony which a single stroke might terminate, while narcotics are administered only for the purpose of killing under the influence of an anæsthetic, seems to be the very pedantry of humanitarianism. The fact is that rules cannot be framed to supersede in every detail the head and heart of the operator.

THE METROPOLITAN ASYLUMS BOARD.

AGAIN another week has passed without a single case of small-pox being removed to the metropolitan hospitals, and again at the last meeting of the managers was the cry raised that the hospital ships ought to be closed. The managers have, however, a very distinct duty to perform—the removal from London of all cases of small-pox that can be removed; and the hospital ships essentially give opportunity for this to be done. Later, when the managers have learned how small-pox hospitals may be built which will not act as centres of infection, the natural course will be to utilise those in London, but at present there is no alternative but to adopt the course they have determined upon. The guardians of Islington, who have no public health functions, have protested against the expense of keeping open the hospital ships. The managers have, however, become (not of their own seeking, but because of the neglect of other bodies) the hospital providing authority for public health purposes; they must do more than house sick people—they must keep in readiness the machinery for isolating cases of infectious disease, and thus aid in the prevention of epidemic prevalence. The money spent in maintaining their hospitals in a state of preparedness better serves the public interest than the larger sum which would be required for providing accommodation for numerous cases which would result if small-pox were treated in London. The statement which was made by the Islington representative, that every small-pox patient costs £800, simply conveys to the minds of those conversant with hospital administration the smallness of the number of cases under treatment. The letter of the Islington guardians has now been referred to the Ambulance Committee for consideration and report; their decision will be freely accepted by the ratepayers, for no member of the board more thoroughly possesses the public confidence than the chairman of this committee.

RABIES IN DEER.

THE recent outbreak of rabies among the deer in Richmond Park will perhaps direct attention to the hitherto almost entirely overlooked destruction caused by this disease in other than the human and canine species, and afford an additional reason for strenuous efforts to rid the country of it once and for ever. Almost daily we receive reports of heavy losses sustained among horses, sheep, and cattle, through their being inoculated by rabid dogs; and this incident in Richmond Park is far from being a novel one. In Fleming's "Animal Plagues" and in his "Rabies and Hydrophobia" allusion is frequently made to the occurrence of the malady in deer, as well as in foxes, wolves, and other *feræ naturæ*. It is well known that of all the animals in India the one most liable to rabies is the jackal, and that it generally is the medium of infection; as when rabid it has no fear, and becomes extremely aggressive. It appears that in last October, when rabies was prevalent in the suburbs of London, a rabid dog was seen in Richmond Park, and it was noticed that some of the deer were bitten by it. In the course of time one or two of these creatures showed the disease, the symptoms, however, being more of the paralytic than the furious form, and were therefore at first misleading, the presence of rabies not being suspected. Soon others became affected, however, and both forms of the disease were manifested, those which were furious biting and butting their fellows. Whether the bites of the rabid deer were productive of rabies in those bitten by them, or whether all had been infected by the dog, cannot be clearly ascertained; certain it is, however, that a large number of them have died, or been killed because of being affected. Some accounts report considerably over a hundred lost in this way, and measures of isolation and segregation have probably prevented further mischief. That the disease was rabies there is no reason to doubt, as inoculation with portions of the brain and spinal cord of deer which had perished from it has produced the malady in rabbits. These experiments were carried out at the Brown Institution. It is to be hoped that adequate prophylactic measures, and notably the systematic adoption of muzzling of dogs, to which we advert in another column, may be enforced, so that in the course of a year or two we may hear no more of such a terrifying scourge, which has been allowed free play far too long. It now exists in at least six counties in England.

SMALL-POX AND VACCINATION.

THE determined opposition to the Vaccination Acts at Leicester has led to a sad exhibition of violence in that town. According to reports in the daily press, an auctioneer was assaulted and driven into the police-station because he had attempted to sell the goods of a man who had refused to pay a penalty inflicted by a magistrate for non-compliance with the Vaccination Act. Leicester will one day have serious cause to regret the reckless wilfulness with which it refuses to learn that vaccination, and vaccination alone, will protect against small-pox. Not long since we pointed out that the system of isolation which is rigorously practised in Leicester is dependent for its efficacy upon the vaccination and revaccination of the hospital attendants. Leicester, therefore, is obliged to rely upon vaccination; but the time will certainly come when even the method of removing to hospital, not only the sick but also those who are exposed to them, as practised in that town, will fail to protect sufficiently the population. The story that comes from Marseilles might be studied with advantage. This town resembles Leicester in so far that there is no compulsory enforcement of vaccination. It is now stated that the mortality from small-pox among the Marseillaise was last year greater than that assigned to any other cause except diseases of the respiratory organs, which but slightly exceeded it. The total mortality from small-pox was said to be over 2000 in a population of 375,000.

HEREDITY.

WE read in a contemporary that at the request of the Crown Prince of Germany, Professor Virchow has endeavoured to trace in the long line of the Hohenzollern Princes persistent physiognomic peculiarities such as have been observed in the Stuarts, Bourbons, Hapsberg, St. Albans family, and many others; and he is said to have found that the physiognomic characteristics of the Hohenzollerns seem to have split up into several types, which are in some cases strikingly apparent, and then disappear for some generations. Evidence of a like kind might, we imagine, be obtained readily from any family that has long been settled in the same place, though in these days of change of locality it is not always easy to trace family peculiarities for more than a generation or two.

THE CONJOINT COLLEGES AND A DEGREE IN MEDICINE.

A PETITION has been sent in to the authorities of the Royal Colleges of Physicians and Surgeons of London by the teachers in the metropolitan medical schools praying that earnest endeavours may be made to obtain the power of granting a degree in medicine. There are four qualifications or conditions in the petition, to one or more of which each signer has testified his assent—viz., (1) that the degree should be granted only to those who have received some portion of their medical education in London; (2) that some addition should be made to the present examinations in arts; (3) that some additions should be made to the present examinations in science; and (4) that some addition should be made to the present examinations in professional subjects. The first of these conditions finds great favour with the signers of the petition, and the other three are also well supported.

ALMÉN'S TEST FOR SUGAR.

Of all tests for sugar in urine, Fehling's is undoubtedly the most satisfactory. The only objection that can be urged against it is the difficulty of preserving it a sufficient length of time, so that unless recently prepared it may lead to fallacious results, owing to stale solutions having a tendency to throw down the suboxide of copper spontaneously when heated. This of course is a great disadvantage to practitioners, who may be seldom called upon to use the test, and are at a distance from manufacturing chemists from whom they may procure a fresh supply. To remedy this Professor Alméu of Upsala has improved the old bismuth test for sugar, and has prepared a solution which has the advantage of keeping unchanged for years, and being at the same time an extremely delicate test for sugar in urine. It consists of a solution of bismuth subnitrate, with caustic soda and potassio-sodium tartrate. In testing for sugar, the albumen, if present, must be first removed by precipitation by heat and acid, and one part of the solution treated with ten of the urine, when if sugar is present the bismuth will be deposited in a metallic state. The test is sufficiently delicate to detect sugar in the proportion of only ·05 per cent. This test, as we have already said, is chiefly valuable on account of its preservative qualities, keeping well on board ship and in hot climates, though we doubt if it will supersede the use of Fehling's solution, especially as the latter is now supplied in hermetically sealed capsules which preserve the test for a considerable time.

DENTAL DISEASE IN SAVAGES.

DR. WHITNEY writing from Honolulu, describes in the *British Journal of Dental Science* the bleached skeletons of Kauai, and points out that it is a great mistake to believe the "noble savage" enjoys an immunity from suffering due to disease affecting his teeth; in spite of the simple nature of his food and his out-door life, he still has toothache. Dr. Whitney found both superior and inferior maxillaries, but none had complete dentures. This does not take into account the loss of the anterior lower and, less frequently, upper teeth, which were knocked out to express their grief at the death of a favourite chief, as was their universal custom in those times. Some had lost but one or two teeth, others the greater portion of the molars; while not infrequently the anteriors showed decay upon their surfaces, or had left the traces of alveolar abscess. In several cases traces existed of much suffering, caused by the eruption of the inferior third molars, and in several by the superior. One specimen showed the ravages of salivary calculi, but, as a general rule, there was but little tartar upon the teeth. No instances of erosion were met with, but many of the teeth were much worn by use. There was one case of ankylosis of the jaw. Several had exostosis. The effects of alveolar abscess were very frequently seen, sometimes leaving but a small opening through the outer plate of the jaw, in others the whole outer plate being gone. Dr. Whitney found the antrum to vary greatly in size. On the whole, the teeth were set in a regular arch, but there were a few instances of irregularity. In uncovering two skeletons lying side by side, it was seen that both were females, one much older than the other, and in them the peculiar dental irregularity of the one was exactly repeated in the other.

CHOLERA IN SOUTH AMERICA.

CHOLERA is believed to have ceased as an epidemic in the various parts of South America that have been attacked. Its ravages in some districts have been very severe. Thus, according to local information, there had been in Santiago, up to about the end of February, a cholera death-rate equal to 10,000 per million living, as compared with a rate of 2422 and 913 per million during the epidemics of 1848-9 and 1854 respectively in England and Wales. The city stands upon an alluvial soil largely saturated with sewage matter, which courses about in open drains, and its sanitary condition generally is such as to serve as a strong predisposing cause to the spread of such a disease as cholera. Having regard to the wide extent of the infected area, and to the fact that the conditions so largely favour the propagation of the infection, there are strong grounds for fearing that with the return of summer weather a recrudescence of cholera may take place, and that the present abatement is due rather to the winter period than to the adoption of proper precautions in favour of improved healthiness. In Santiago, especially, there is urgent need for a proper system of sewerage and drainage, and it is to be hoped that the authorities will not defer providing it until they have had another fatal lesson in the form of a renewed cholera epidemic.

THE CIVIL WAR, 1643.

HISTORIANS have advanced from time to time many conjectures to account for the slow conduct of the war between Parliament and the Crown during its earlier stages. Some have thought that the leaders on both sides equally feared a decided success; others have attributed the delays and failures in strategy to the incompetency of the generals or the undisciplined state of the troops. None, however, seem to have hit the real reason, which, nevertheless, is graphically described by an eye-witness, the celebrated Dr. Thomas Willis, who was with the King at Oxford. According to Dr. Willis, neither party after the siege of Reading were able to take the field for many months, owing to the great mortality in both camps, which "grew so grievous that in a short time after, either side left off, and from that time for many months fought, not with the enemy, but with the disease; as if there had not been leisure to turn aside to another kind of death, this deadly disease increasing, they being already overthrown by fate, and as it were falling down before this one death." It is strange that this statement should so long have escaped the notice of historians, especially in these days of minute research; but, now that attention is drawn to it, there can be little doubt that many circumstances will be explained that have hitherto looked suspicious in the conduct and action of some of the commanders. Thus, how could the Earl of Essex make a vigorous campaign when the London apprentices, who formed the bulk of his regiments, were dying so fast that, as Willis distinctly says, he lost the great part of his men, and had to remain pitched in camp on the banks of the Thames. The excessive mortality also accounts for

Digitized by Google

the surrender of Reading by the King's officer, who has been generally credited with treason; yet it was during the siege that the camp fever first broke out, and the garrison on their surrender carried the disease with them to the main body of the King's army, who suffered "not much less" than Essex's camp on the Thames, which again accounts for the supineness of the Royalists and their hesitancy in not taking advantage of the condition of the enemy. For, as Willis describes it, the foot soldiers (which it chiefly invaded) being packed together in close houses in the villages, "they filled all things with filthiness and unwholesome nastiness and stinking odours, they fell sick by troops, and as it were by squadrons." Willis is particular to tell us that this great mortality was due to typhus—a true camp fever, and not of the nature of the plague; and that the epidemic did not spread beyond ten miles of the infected camps, the surrounding counties being healthy.

EPITHELIOMA OF THE KIDNEY.

THE proceedings of the Paris Anatomical Society (*Progrès Médical*, April 23rd) make mention of the histological examination by M. Cornil of a rare tumour of the kidney removed during life by Dr. Pean. The portion examined included a cyst filled with blood. This cyst had a wall of new growth, surrounded by the capsule of the kidney, beneath which atrophied anatomical elements of the organ were seen. In the new growth were seen hæmorrhagic areas and calcified fibrous tracts; and budding into the cyst were grey, semi-transparent vegetations containing small ovoidal cavities, lined by a single layer of clear epithelial cells, with nuclei near their base. The lumen of the cavities was empty, and their wall contained capillaries arising from vessels running mostly longitudinally. The resemblance to uriniferous tubules was striking. In places there were cavities of larger size filled with red corpuscles, suggestive of intertubular hæmorrhage. Some of the cells were filled with fat-globules, others with fat-crystals; and the intermediate tissue contained fat or calcareous material. The case is recorded as "hæmorrhagic epithelioma"; and M. Cornil pointed out that it belonged to the class described by Sabourin under the head of "adenoma," growths which, although structurally simple, were clinically to be regarded as cancers. Nevertheless, they generally remain confined within the capsule of the kidney and undergo calcareous transformation.

THE ADULTERATION OF PEPPER.

THE study of pepper adulteration has progressed considerably of late. Dr. Campbell Brown of Liverpool has described an adulterant which has hitherto been little known. This is the great millet (*Sorghum vulgare*), one of the most important of the Indian cereals. In Professor Church's recent and valuable book it is described as "joár," but several synonyms are given as well as excellent illustrations. Dr. Campbell Brown describes it as "dhoura," which is perhaps the name by which it is known in the English market. Of course, its addition to pepper is a mere common fraudulent adulteration. Another valuable contribution to our knowledge is contained in some articles which appeared last month in our new contemporary, *The Produce Markets Review*. In these articles the fashionable adulterant miscalled *poivrette* is described, and its influence on the trade discussed. Poivrette is obtained by grinding waste olive-stones, and is totally useless as a substitute for pepper. The author concludes from a study of trade statistics that some 600 tons a year of adulterants have been used in the pepper for the last year or two. The actual adulteration has, the author argues from good evidence, been effected by the wholesale grinders, and not by retailers, who were probably ignorant of it. The adulterant used was poivrette, the annual profit which has accrued to a presumably small number of dishonest seed grinders, has on the above [illegible] amounted to £67,000. This ought to stimulate public analysts to increased exertions. The subject of long pepper, to which we lately alluded, is also discussed in these articles. Long pepper, it appears, sells for 6½*d.* a pound, while white pepper costs 11½*d.* As we before pointed out, long pepper is more or less similar, though greatly inferior, to true pepper. The temptation to use it for fraudulent purposes is obvious.

DR. PEACAN'S TREATMENT OF CHOLERA.

DR. L. PEACAN of Buenos Ayres warmly recommends a plan which he has for many years past pursued with much success in the management of cholera. When a typical case with vomiting and diarrhœa comes before him, he immediately applies a cautery behind the right ear over the condyle of the lower jaw, with the object of stimulating the pneumogastric, and thus paralysing the action of the sympathetic on the abdomen. He then administers six centigrammes (sixth-sevenths of a grain) of calomel, which dose is repeated every five hours. Half an hour after taking the first of these powders a mixture is commenced consisting of phosphoric acid, carbolic acid, tincture of opium, tincture of ginger, chloric ether, and mint-water, which is supposed to arrest vomiting and diarrhœa, to allay thirst, and to calm spasm—being, indeed, he states, sufficient to cure mild cases by itself. When the cramps are severe, ten drops of Battley's sedative solution of opium is added; and when there is marked prostration of the nervous system, tincture of coca. If the diarrhœa continues, three grammes (forty-six grains) of glycerole of tannin are given in coffee three or four times a day, and forty centigrammes (six grains) of Dover's powder for three or four nights in succession. The patients are allowed to have as much sulphuric acid lemonade as they care for. In addition to internal medication, warm frictions and sinapisms are applied, especially over the epigastrium.

THE ANATOMICAL SOCIETY.

THE inaugural meeting of this Society was held on the 6th inst. Professor Humphry was elected to the chair, and letters expressing approval were read. It was then proposed "That an Anatomical Society be formed, and that it be called the Anatomical Society of Great Britain and Ireland." This resolution was carried. Next, it was carried *nem. con.* "That the scope and object of the Society be the anatomy, embryology, and histology of man and of animals, in so far as they throw light upon the structure of man." Professor Humphry was then elected president, and delivered an address, which will be found in another part of our present issue. Mr. C. B. Lockwood was elected hon. secretary, and a committee was appointed to report upon the constitution of the Society. The first meeting will be held at an early date and duly announced.

DANGERS OF AIR-GUNS.

AIR-GUNS are dangerous playthings. Last week one of the gentlemen cadets at Woolwich aimed one of these weapons at a boy who was carrying a basket near the academy, not thinking that the air-gun could carry fifty yards, which was about the distance at which the boy was. However, the little bullet, which was about the size of a swan-shot, hit the boy on the cheek and embedded itself in the masseter, where it will probably do no great harm. Had it entered the eyeball, the accident would have been fraught with much more serious consequences. It is to be hoped that this will prove a warning to all persons who indulge in such dangerous toys not to point them except at a target.

...MORTALITY AT WILLESDEN.

DR. ...ANTHW...TE, in his annual report on the health of the Willesden Local Board District, draws attention to a matter of grave importance. He has on more than one occasion directed ...tice to a large infantile mortality. During 1886 the nu...ber of deaths under one year of age amounted to 16·7 on every hundred births, and in view of this special inquiry was made into the matter. The result has been to show that some very decided action is needed under the provisions of the Infant Protection Act, and that this fatality is in large amount brought about in the case of infants born in a metropolitan lying-in hospital where single as well as married women are received. During 1886 there occurred six deaths under two years of age in one house, two deaths under three months in a second, two deaths under one month in a third, and in each of seven other houses a single death occurred. In all these instances the children were in some way or other connected with the lying-in hospital referred to. In seven other cases of infantile deaths the children came from elsewhere. There is, of course, no suggestion that any hospital or other authorities are in any way responsible for this fatality; but it seems very obvious that a large number of so-called "nurse" children are sent into the Willesden district, and that a very undue proportion of them die there. Dr. Branthwaite very properly advises that the legal adviser to the local authority should at once take such action as may be possible in order to bring the many houses involved under such control as can be brought to bear upon them. We hope, in the next report, to see that some very decided action has been taken in the matter.

EFFECTS OF HOT-AIR BATHS ON ASSIMILATION.

IN a paper by Dr. Garin of St. Petersburg on the effects of hot-air baths on healthy subjects, and on those suffering from kidney disease, it is stated, as the result of his researches, that the sudorific action of hot air produces an increase in the quantity of the nitrogenous elements of food assimilated. In healthy subjects it was found that after a course of hot-air baths lasting for five days the nitrogen assimilated was greater than before the baths, though less than during their continuance. This, however, did not appear to be always the case with patients suffering from nephritis. Again, the ratio of the urinary nitrogen to the nitrogen assimilated—that is to say, the nitrogenous metabolism—was decidedly increased both during and after the baths, the subsequent effect being more marked in the case of nephritic patients than in that of persons in good health, though not in either case so great as the effect observed while the baths were in progress.

THE REPUTED SUICIDE OF SCORPIONS.

A MEMOIR upon this subject, of much interest and value, has just appeared in the Proceedings of the Royal Society. A statement has long passed current in works on zoology that a scorpion when placed under such circumstances as to preclude the possibility of escaping with life—such, for example, as surrounding it with a ring of red-hot embers—will deliberately sting itself upon its own back, and put an end to its sufferings by destroying its own life. This legend, which is believed to emanate from Spain, though denied by some, has received the countenance of several respectable authorities. It has now been put to the proof and ascertained to be incorrect by the scientific investigation of Dr. A. Bourne, the Professor of Biology in the Presidency College, Madras. It may be noted, in the first place, that there are several species of scorpions, and, as Professor Ray Lankester (who has himself made some experiments upon the point) remarks, it is important that the species should be determined, since one species may act in this way whilst others may not. The first question Dr. Bourne set himself to solve was the power of the scorpion to sting itself at all, and he found that the movements of the sting are remarkably free—so much so, indeed, that if a dead but still limp scorpion be taken, the last four segments of the tail are about the only portions of the body where the scorpion is incapable of stinging itself. Further, when a scorpion is placed in very unpleasant circumstances it not unfrequently lashes its tail about and causes actual penetration of its own integument. But numerous experiments performed, both by stimulating scorpions to fight and by artificially injecting the poison, which is easily obtained from the gland by pressure into the bodies of these animals, show that the poison of a scorpion is quite powerless to kill the same individual of the same or even of another species. Experiments made in the same way with other animals show that the poison is very rapidly fatal to a thelyphonus, which is an animal closely allied in form and poisonous faculty to a scorpion, less rapidly to a spider, and much less rapidly to an insect. On injecting the poison into the leg of a cockroach or of a cricket the injured leg became paralysed, but no pain appeared to be produced. The slow and comparatively feeble action of the poison on insects Dr. Bourne attributes, with great probability, to the very inefficient circulation of the blood in that class as compared with arachnida. When two scorpions fight, they may repeatedly be observed to sting one another with little or no effect, and the stronger kills the weaker by actually pulling it to pieces with its chelicerae, and then proceeds to feast upon its victim. On making experiments with heat, as by concentrating the sun's rays with a burning-glass upon the animal's back or elsewhere, the animal lashes out with its sting and endeavours to strike away the source of irritation. If placed in water at 43° C., scorpions quickly die; and they do not appear to be able to stand a dry heat much above 50° C., falling into a kind of heat coma and becoming very sluggish.

"THE SPECTACLE MISSION."

A PROVINCIAL contemporary contains an account of a new missionary enterprise—one for distributing spectacles among the poor. This may seem at first sight a very prosaic thing to do, but we recognise in it the very genius of kindness. "I was eyes to the blind" was one of the most excusable boasts of Job in his moments of pardonable complacency. Such may be the satisfaction of Dr. Edward Waring of Maida Vale, who is credited with initiating this piece of benevolence among the inmates of St. Giles's workhouse and the Cleveland-street Sick Asylum years ago. Such a service implies much trouble and time. It is of little use to supply spectacles to the poor without much personal trouble to suit the glasses to sight. We can only hope that Dr. Waring's example will be fruitful, and that the intolerable irksomeness of life in those who have the disposition to work without the means of doing so will be extensively mitigated.

MASSAGE IN CATARRH OF THE BILE-DUCT.

DR. GOPADZE publishes in the Proceedings of the Caucasian Medical Society an account of fourteen cases of catarrh of the bile-duct in which massage proved of great service. The symptoms were loss of weight, malnutrition, eructations, tympanites, diarrhœa or constipation, admixture of blood with the stools, loss of appetite, &c. In a week's time from the commencement of systematic massage a marked improvement invariably took place. The author complains that massage is as yet but very little practised in Russia, and that its use is chiefly confined to surgical clinics. Professor Manassein, the editor of the *Vrach*, replies, however, that massage has been for some time past largely practised

Digitized by Google

in his own and many other medical clinics, and that the three graduation dissertations which have treated of the subject, one of them from the pen of Dr. Gopadze himself, were all founded on work done in the physicians' wards. Indeed, though Dr. Gopadze may be inclined to underrate the attention bestowed on massage in Russia, the back numbers of the *Vrach* and THE LANCET would show him that the observations of himself and his countrymen on its value in many different affections are recognised both in Russia and abroad as worthy of attention.

THE CENTENARY OF COLUMBIA COLLEGE, NEW YORK.

LAST month Columbia College celebrated with appropriate ceremonies the one hundredth anniversary of its revival after the Revolution. In 1787 it was reorganised by an Act of the State Legislature, which confirmed the Royal Charter granted in 1754 for the establishment of a College in New York, and also changed the name of the institution from King's College to Columbia College. The medical school was first established in 1767, and strengthened in 1787 by the appointment of a dean of the Faculty and several professors. In the beginning of the present century Dr. David Hosack was professor of botany and materia medica. In 1813 the school was consolidated with the New York College of Physicians, which remained entirely distinct from Columbia College until 1860, when it became formally recognised as the medical department of the institution. The number of medical students at present in attendance is 604, and the munificent Vanderbilt benefactions will without doubt eventually, if not sunk in bricks and mortar, make the school the most completely equipped and extensively appointed centre of medical teaching in the United States.

INTELLECTUAL EVOLUTION.

"INTELLECTUAL EVOLUTION, as represented by modern civilisation, will, by overcrowding, the unequal distribution of wealth, and social changes incidental to these two factors, lead to an increase of the tendencies to disease, and therefore to physiological dissolution," writes Dr. F. W. Mott in the *Edinburgh Medical Journal* of April, 1887. The writer has tried to bring together facts tending to prove that a "racial" existence, like that of the units of which the race is composed, has periods of infancy, youth, maturity, old age, and decay; and that the same factors which lead to early decay and dissolution in individual organisms also tend to the same result in the race. Dr. Mott throughout lays stress on the necessary and simultaneous inter-action and inter-relation, or mutual tension, between evolution and dissolution, growth and decay, rise and fall, development and degradation.

PROPOSED SYSTEMATIC MUZZLING.

THERE seems now to be a more general recognition of the advisability of the adoption in a systematic manner of the muzzling order, and doubtless ere long we may expect the re-issue of the edict from Sir Charles Warren's official centre; but this time the order should apply to the whole of Great Britain, and should be put in force in a thorough and rigid manner for a period of at least six months. The necessity for the adoption of this measure is based on the ground of an increase of rabies and allied disorders, together with its consequences to human beings, as proved by the published statistics; and the increasing confidence on the part of the public in the efficacy of the muzzle, as well as in its real kindliness, will serve to facilitate the administration of the police order. The rare immunity from rabies and hydrophobia enjoyed by Berlin for a period of nine years, owing to [illegible] with which the canine code is carried out [illegible] irrefragable proof of the general mode of origin [illegible] spread of rabies, but is in itself a complete [illegible]ument in favour of the adoption of a similar code.

THE DELICACY OF SPECTROSCOPIC REACTION IN GASES.

AT the suggestion of Sir Henry Roscoe, Mr. T. W. Best has made an interesting series of experiments on this subject which has recently been communicated to the Manchester Literary and Philosophical Society. The author mixed the pure and perfectly dry gases in eudiometers provided with aluminium electrodes, which were connected with an induction coil and Leyden jar. The light of the discharge was then focussed upon the slit of a one-prism spectroscope. The only gases experimented upon were hydrogen, nitrogen, and oxygen, but it may be hoped that others will shortly be examined. When nitrogen is added to hydrogen at ordinary atmospheric pressure, the least quantity of the former element that can be detected is 1·1 per cent. At the same pressure as little as 0·25 per cent. of hydrogen can be detected in nitrogen. This curious difference is also observed with mixtures of nitrogen and oxygen. As little as 0·8 per cent. of nitrogen can be detected in oxygen, whereas no less than 4·5 per cent of oxygen gives a visible spectrum in nitrogen. At lower pressures the results are somewhat different, the least quantity of nitrogen perceptible in hydrogen being at ten inches and a half 3·6, and at three inches and a half 2·5. The experiments are well worth extending. The limits of delicacy with gases containing carbon would be very interesting.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.

OWING to the considerable increase in numbers of the students attending the above school, it has been found necessary to enlarge the new laboratory in which the course of practical physiology is conducted. Accommodation has been provided for thirty additional students, and the lighting of the laboratory has been greatly improved. Two rooms have been fitted up, one as a lecturer's room and the other as a workroom for the demonstrator and assistants. These alterations, with those made when the anatomical department was enlarged and improved some eighteen months ago, have involved large expenditure on the part of the Medical School.

UNDER ETHER.

THE effects of ether and other drugs when administered as anæsthetics have been often and carefully studied by the usual methods of scientific observation, but we do not remember ever having seen such a detailed description of the subjective impressions thus produced as that which has been recorded recently by an American practitioner, Dr. G. E. Shoemaker. In his case the anæsthetic used was ether, and it is curious to notice how the stage of stupor seemed to form, as it were, a prolongation of the earlier stage of excitement, and how some trace of the latter seemed always to persist as a partial wakefulness of intellect, though without the sense of pain, till at last it drew him through a play of intoxicated fancy out of his torpor and back to the daylight of clear intelligence. His description does, indeed, suggest a doubt whether the degree of anæsthesia attained in this instance was as deep as usual. He remarks that, though there was no pain, a most disagreeable sensation never left him. He seems also to have been dimly aware that something was being done to him which was neither right nor pleasant. A confused whizzing sound and a visual sense of oscillation were perceived,

Digitized by Google

nd he could register mentally the beginning of the ›turn to consciousness. It may be doubted whether ich a degree of intelligent, even though drowsy, per- ›ption is consistent with really deep etherisation. Had ıloroform been employed, it is still less probable that ıe stimulant property possessed by the drug should so ır have survived in the narcotism which it initiates as › awaken or maintain any such distinct mental impres- ons. Ether, as is well known, possesses this property in greater degree than chloroform. It is this which consti- ıtes at once its chief disadvantage as an effectual anæs- ıetic and its chief recommendation on the ground of safety. robably the method of producing anæsthesia most likely › satisfy its claim to acceptance as compared with that f its more powerful rival is its use in combination with hloroform, a practice now far from uncommon.

THE COURT PHYSICIANS.

SIR WILLIAM GULL, being the senior Physician Extra- rdinary to the Queen, succeeds the late lamented Dr. Vilson Fox as one of the Physicians in Ordinary. Dr. Reid, rho has been for some years Her Majesty's Resident ledical Attendant, has been appointed one of the Physicians :xtraordinary. A contemporary society journal states that ir William Jenner only attends the Queen when "Her lajesty is really unwell." As a matter of fact, Sir William leeps at the Castle almost every Saturday night when the ›ourt is at Windsor.

MPORTANT DECISION AS TO SCHOOL CLOSING.

IN commenting in a recent issue on the annual report of he medical officer of health for Barnsley, we drew attention o the circumstance that one large elementary school had ailed to comply with the notice to close which was ssued by the sanitary authority on account of the pre- ralence of scarlet fever. We have since then received nformation from Dr. Sadler to the effect that the school, hough a voluntarily supported one, received an annual rant from the Education Department, and that the failure o comply with the request of the sanitary authority was rought under the notice of that department and also of he Local Government Board. Some little time was allowed o elapse before the sanitary authority heard again, but they ıave now been informed that the managers of the school ıave been communicated with, and that in consequence of heir neglect the Education Department decline to make any rant to the school this year. In the case of such a school, his amounts to the imposition of a very substantial ›ecuniary fine, and it is well that both sanitary authorities ınd school managers should know that the clause of the Education Code which deals with this subject is intended to ›e acted upon, and that any failure to comply with the ıuthorised notice of the authority will be met by the loss ›f the Government grant.

TUBERCLE IN THE COW.

THE cowkeepers and farmers of Hull have had their ıttention drawn to the dangers of tuberculosis among their ›attle by Dr. J. W. Mason, medical officer of health, who lelivered an interesting lecture on the subject at a meeting ›f dairymen last week. Dr. Mason urged upon them the importance of slaughtering all animals affected with this lisease, and stated that while in the early stage the meat ›ould be eaten, in the later it was only fit to be destroyed. He discussed the risks to milk drinkers, and pointed out that Hull received 40,000 pints of milk per day from cows living n the town, and an equal amount from cows outside, over whom the corporation had no authority, and he supported the view of Dr. Hime and the Bradford Corporation that authorities ought to be able to exercise control over neighbouring areas supplying the town population with milk. Members of the Association who joined in the dis- cussion expressed their desire for legislation which would enable infected animals to be seized and slaughtered, and would add tuberculosis to the list of diseases dealt with under the Contagious Diseases (Animals) Act. The subject is obviously one of great importance, for although there is much reason for thinking that human and bovine tubercle are not identical, Dr. Creighton has adduced considerable evidence to show that man may suffer from the bovine variety. Certainly the milk of tuberculous cows ought not to be sold, and the only safe course is to slaughter all animals infected with the malady.

THE REGISTRATION OF ARCHITECTS.

ARCHITECTS have been slow to claim the rights which have long since been accorded to other professions; but at last a movement has been made which will in all probability end in the granting of licences to practise to those architects who are competent to perform the responsible duties which devolve upon them. A large meeting was held at St. James's Hall on the 4th inst., which was called by the Architectural Federation Committee, who had drafted a Bill which in principle resembles that of the Medical Acts. It is probable that some modification of this measure will be required before its acceptance is sufficiently general to enable it to become law. With the intention of the Bill we are entirely in accord; there is reason for the public to be able to dis- tinguish between qualified and unqualified architects, as there is also for them to be able to know the professional position of medical men. It will doubtless be necessary to place upon the register in the first instance many who although now engaged in practice, have but scanty claim to this position; but this is inevitable, and in course of time the difficulty will be overcome. The intimate relation which, it is now recognised, exists between ill-health and imperfect house construction renders the Bill deserving of the support of the medical profession.

LUMINOUS PAINT IN THEATRES.

HERR STEHLE, the Government Inspector of the Royal Bavarian Court Theatre, has, according to *Iron*, given high testimony to the use of luminous paint as a safeguard against panic in theatres. Any explosion or disaster with gas leaves the exit passage of the theatre in total darkness, and even if additional oil lamps were used, they would probably be extinguished by the air concussion. In the above-named theatre inscriptions in luminous paint are suspended over the exit passages, which direct the audience to the "way out" (*Ausgang*). "These placards, in spite of being exposed to the very poor light of the corridors in the daytime and the gaslight in the evening, are so luminous after the gas has been turned out that anyone can gain the stairs in each corridor without difficulty." The precaution is so simple and inexpensive that we wonder it is not immediately adopted in all theatres. Indeed, we see no reason why its use should not be made compulsory. Surely some provision of the kind might be included in the Theatres Bill now before Parliament.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Johann Anger, the well-known Carlsbad "bath-physician," at the age of seventy-two.—Dr. Fleitas y Lemus, Director of the Hospitale de Higiene in Havana.

Digitized by Google

SURGICAL OPERATIONS ON THE BRAIN.

AT the meeting of the New York Neurological Society, held on April 5th, two interesting examples of "cerebral surgery" were recorded. The first was the case of a man forty-two years of age, who suffered from left lateral hemianopsia, slight dilatation of the left pupil, awkward gait, and double optic neuritis. A large tumour in the right occipital lobe was diagnosed, and Dr. Weir proceeded to remove it. The mass removed weighed five ounces and a quarter, and the operation was attended with very troublesome hæmorrhage, for which the wound was plugged. Unfortunately the bleeding recurred, and the man died from it. The other case was one of unilateral (left) convulsions, followed by paralysis of the left side of the face, then of the left arm, and then of the left leg. A tumour was diagnosed in the right motor area, and the skull was opened and the brain explored with a hypodermic syringe without any result. The patient died, and at the necropsy three cysts were found lying close together in a line deep in the white matter of the right hemisphere, and "in a position to affect the face, arm, and leg centres."

ACTION OF CALOMEL ON BILE.

AN account of a number of observations made in the laboratory of Professor Tumas in Warsaw, and published in the *Vrach*, points to the antiseptic action of calomel on bile. It was found that when fresh bile was mixed with calomel and kept at the temperature of 12° R. (59° F.) for several days its smell and its colour changed but little, whereas another portion of the same specimen, unmixed with calomel, kept under similar conditions, rapidly became putrid and turned to a reddish colour. Again, a smaller admixture of calomel produced a partial effect only. This antiseptic effect appears to be due to the conversion of calomel in an alkaline medium into suboxide of mercury, which converts bilirubine into biliverdine—thus, $C_{16}H_{18}N_2O_3 + 2Hg_2O = C_{16}H_{18}N_2O_4 + HgO + 3Hg$, mercuric oxide and metallic mercury being also formed. If an experiment is made on alkaline bile by mixing it with calomel a distinct deposit of metallic mercury is easily obtained.

EFFECTS OF WARM ABDOMINAL COMPRESSES.

DR. T. T. LEVINSON, who has been engaged in investigating the effects of warm abdominal compresses under the direction of Professor Manassein of St. Petersburg, finds that they distinctly promote nitrogenous change in the body, the quantity of urine passed and the amount of uric acid excreted being also increased, as well as the assimilation of the nitrogenous elements by the body.

THE COMPULSORY DETENTION IN WORKHOUSES OF PATIENTS WITH VENEREAL DISEASES.

IN our issue of last week there appeared, on p. 954, a letter from Mr. A. F. Mickle, M.B., advocating the necessity of acquiring powers to detain until well all patients suffering from venereal diseases in our Poor Law and other institutions. A correspondent calls our attention to the fact that, so far as workhouses are concerned, such power already exists as to syphilitic diseases, and presumably also to gonorrhœa. It is the Act 30 and 31 Vict., the Poor-law Amendment Act, c. 106, s. 22, which provides for the compulsory detention in workhouses of persons afflicted with contagious disease; and the Royal Commissioners appointed in 1870 to inquire into the Contagious Diseases Acts were advised that this includes syphilis. The clause is very complete and stringent, conferring ample powers on the guardians, the master, and the medical officer of each workhouse to detain such patients until the medical officer has certified as to their freedom from disease. If from any reason this power has been permitted to fall into abeyance, or has been exercised with laxity, it is of the greatest importance that it should in future be rigidly enforced.

THE ELECTION AT ST. THOMAS'S.

WE understand that Walter Baugh Hadden, M.D. Lond., M.R.C.P., and Theodore Dyke Acland, M.D. Oxon., M.R.C.P., have been elected assistant-physicians to St. Thomas's Hospital.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Dr. F. Renk of Munich has been appointed to take charge of the Imperial Sanitary Bureau, in succession to Professor Wolffhügel, who has gone to Göttingen.

Halle.—Dr. Zopf, *Privat Docent* in Botany, has been granted the position of an Extraordinary Professor.

Königsberg.—Dr. Branco of Berlin has been offered the Professorship of Mineralogy and Geology.

Montpelier.—The Faculty of Medicine has recommended M. Kiener, principal medical officer of the Military Hospital, for the Professorship of Pathological Anatomy and Histology, vacant by the death of M. Estor. In proposing M. Kiener, who is not *agrégé*, the Faculty has taken a new departure, it being the rule hitherto that only those who had the title of *agrégé* or assistant professor could hope to obtain the higher post.

DR. J. A. MARSTON, Deputy Surgeon-General, head of the Sanitary Branch of the Army Medical Department, is, in consequence of the continued indisposition of Dr. De Chaumont, at present discharging the duties attaching to the chair of Military Hygiene at the Medical School at Netley. We regret that we are unable to report any great improvement in the condition of Dr. De Chaumont.

ON the 9th inst., Princess Beatrice opened as a place of recreation the disused burial-ground adjoining the Church of Holy Trinity, Tredegar-square, Bow-road. The whole cost of laying out the ground, which is about an acre in extent, has been defrayed by the Metropolitan Public Gardens Association.

MR. CONDER'S sewage process is said to be now at work successfully at Chichester Barracks. A pamphlet has been forwarded to us in which the results obtained by its means are represented as remarkably satisfactory, but no sufficient details are given as to the *modus operandi*. We are therefore unable to express an opinion on its merits.

ON the 21st ult. the death occurred of Deputy Inspector-General J. G. T. Forbes, R.N., at Pitlochrie, N.B., after a lingering illness, borne with exemplary resignation and fortitude. The deceased, who had some time ago retired from the service, obtained the licence of the Royal College of Surgeons of Edinburgh in 1848.

AS announced in our advertising columns the annual general meeting of the governors of the Royal Medical Benevolent College will be held on the 26th inst., when, in addition to other business, several important alterations in the bye-laws of the College will be proposed by the Council.

WE are requested by the Director-General of the Army Medical Department to state that no examinations for commissions in the Medical Staff of the Army will be held in August next.

Digitized by Google

WE understand that the new and commodious Physiological Laboratories just completed at St. George's Hospital Medical School will be opened on Wednesday, May 18th, at 3 P.M. An address will be delivered on the occasion by Mr. George D. Pollock, consulting surgeon to the hospital.

THE President of the Royal Medical and Chirurgical Society announces that the name of Dr. S. J. Gee has been nominated by the Council as honorary librarian, to fill the vacancy caused by the much-regretted death of Dr. Wilson Fox.

MR. BLAND SUTTON and Dr. Dudley Buxton have been elected honorary members of the Odontological Society, in acknowledgment of the distinguished services they have rendered the science of dental surgery.

THE proposal to erect an Infectious Disease Hospital at Horsham is meeting with much opposition by the residents of the town, and a memorial is to be presented to the Local Government Board against the scheme.

MR. VICTOR HORSLEY, F.R.S., will give at the Royal Institution, on Tuesday, May 17th, the first of a course of three lectures on the Modern Physiology of the Brain and its relation to the Mind.

DR. GRAILY HEWITT has been appointed a Vice-President of the Gynæcological Section at the forthcoming International Medical Congress at Washington.

LORD RAYLEIGH, F.R.S., has been elected Professor, and Dr. John Tyndall, F.R.S., Honorary Professor, of Natural Philosophy at the Royal Institution of Great Britain.

MEETING OF THE GENERAL MEDICAL COUNCIL.

(*Continued from page 989.*)

THURSDAY, MAY 12TH.

MR. MARSHALL, PRESIDENT, IN THE CHAIR.

SIR WM. TURNER moved that the following address to Sir Henry W. Acland be signed and approved by the Council:—

To Sir Henry Wentworth Acland, K.C.B.

We, the members of the General Medical Council, desire to express to you on your retirement from the presidential chair, to which you were elected in July, 1874, our warmest thanks for the invaluable services which you have rendered, as President, during the past thirteen years. We would record that you have with singular devotedness applied yourself to the service of the Council, and that you have conducted its business with a dignity, courtesy, and impartiality which have secured for you the confidence, regard, and affection of its members. We would also recall the fact that you have been a member of the Council since its establishment by Parliament in 1858, and that your action during that long period has had for its object the improvement of medical education, the elevation of the status of the medical profession, and the establishment and maintenance of harmonious co-operation between the Council and the several medical authorities of the United Kingdom. We would also express the hope that you may, in your retirement, have the enjoyment of your well-earned leisure.

Dr. QUAIN seconded the motion, and suggested that Sir H. W. Acland be requested to dine with the Council next week.

The motion was unanimously agreed to.

The debate on Mr. Carter's motion was resumed.

Dr. HUMPHRY said the question was not one of sympathy with the Society of Apothecaries, but a question of carrying out the Medical Act, the great object of which was to enable the different medical bodies to combine in their examinations. A discretion was given to the Medical Council; and it was not only to "think fit" on the subject, but was bound to think fitly, and if it did not it was subject to a *mandamus* from a higher power. It would be absurd for the Medical Council to tell the Privy Council that it would be "injurious to the interest of the public" to adopt the course proposed without stating its reasons. None of the reasons which had been given would have any weight with a sensible body like the Privy Council. He had been astonished that they should have been brought forward by two sensible Scotchmen. One reason assigned was that competition would be injurious; but Parliament had provided for that competition, and the Council could not put forward such an objection. As to the Apothecaries' Society being a trading Society, that fact was known by Parliament, and there was no reason why a trading Society should not give a good examination. It had been stated that the Society had degraded the profession. It had, however, commenced the examination of students, and the Medical Council had extended that examination. As to dispensing medicines, he knew many high-class practitioners who had done the same thing without any degradation whatever. The assertion that the Society of Apothecaries had been the cause of homœopathy was absurd, and it was impossible to assign such a ground of objection to the Society. There was only one proper ground of refusal, and that was that a proper examination could not be given with the aid of the Medical Council; and the question was whether such a statement could be borne out. It was admitted that the Society gave a good examination in its own department; and the Council had power to appoint any number of examiners whose duty it would be to maintain the required standard of examination. Could the Medical Council go to the Privy Council and state that it could not make the examination an adequate one? If it could not, it had no valid objection to offer to the proposed combination.

Mr. COLLINS said he understood the objection which many gentlemen might have to a mixture of trade and profession; but the Council was sitting as a judicial body, and ought to act in that capacity, not simply carrying out the private opinions of its members. One of the privileges conferred by Parliament upon medical practitioners was that they might charge for the medicaments they supplied. Physicians only were prohibited from charging for medicines. As a judicial body the Council was bound to carry out the law. When the Apothecaries' Society's Act was passed, Parliament knew that the members of the Society kept open shop, and yet it gave the Society power to examine in medicine, thus mixing trade and profession. As to the interpretation of the words "if they think fit," if there was any doubt on the subject, the Society of Apothecaries was entitled to the benefit of that doubt. It was quite possible that the young man who sold to Dr. Struthers the 3*s.* 2*d.* worth of medicine at Blackfriars had the diploma of the University of Aberdeen in his pocket. (Laughter.) If the licentiates of the Apothecaries' Society were inferior men, the fault lay chiefly with the teachers who gave them their certificates. The idea of homœopathy and hydropathy having been encouraged by the Society of Apothecaries could not be substantiated, other causes having contributed to the result.

Sir WM. GULL protested against the notion that the Council had no discretion in the matter. He maintained that the Government would not interfere with the discretion of a public body so long as it was exercised *bonâ fide*. His duty as a member of the Council was to consider whether it was desirable to have a Society of Apothecaries at all. He contended that it was not, and that its existence was contrary to the interests of medicine. People did not get well by drugs. When the Prince of Wales was ill of typhoid fever how many doses of medicine did he take? Not four. The question was whether the profession should be set free from the trammels of the past. Medicine was once given even for fractures. It was the powers of nature that effected a cure of disease, and the duty of the medical man was not to give drugs, but to see that nature's powers were not interfered with. He had nothing to say against general practitioners, whom he respected and admired; but he wanted to raise the general tone of the profession, and that object would never be accomplished by maintaining the Society of Apothecaries. There was no reason for appointing examiners in surgery for the Society, seeing that the College of Surgeons was willing to undertake the examinations. Whatever might be said of general practitioners, there was a universal practitioner better than all of them—a warm bed when you are sick.

Dr. QUAIN protested against being considered a pretender in professing to cure disease by administering remedies. He had seen drugs of use in thousands of cases, and where they

Digitized by Google

failed, the fault was not with the drugs, but with the diagnosis.

Mr. MACNAMARA was not going to discuss the merits or demerits of drugs, but he believed it was the general feeling that the request of the Society of Apothecaries should not be granted. He differed from Mr. Simon as to the compulsory signification of the words "if they think fit." Legal opinions on the subject were of little value unless they were delivered from the bench. He maintained that the Act of Parliament had actually disfranchised the Society of Apothecaries. Its qualifications were stated not to be registrable, and it was for the Medical Council to decide whether they should be made registrable. There was no adequate ground for the adoption of that course, and he hoped that the application for the appointment of additional examiners would not be granted. It would, he believed, be to the advantage of the profession and the public to prevent the appointment of such examiners, which would, in his opinion, be a retrograde step.

Dr. GLOVER protested against Sir Wm. Gull's statement as to the uselessness of drugs, and said that his speech was rather directed against physicians and the whole medical profession than against drugs. It had been said that if the virtue of cinchona had been discovered a little earlier the life of Oliver Cromwell might have been prolonged for some years. The action of the two Colleges was, in his view, an additional reason for granting the prayer of the Society of Apothecaries. He had been for many years one of a number of persons who had tried to diminish the number of licensing corporations by the action of the Legislature. The Legislature, however, had declined to reduce the number in the way desired; and that being so, he now declined to be the executioner of an old corporation that had done its work well for seventy years. If it was disestablished, it should be by the same Parliament that had called it into existence. His experience agreed with that of Mr. Wheelhouse, that low professional conduct was rarely exhibited by licentiates of the Society of Apothecaries, who had always been distinguished for their honourable behaviour as men and their competency as practitioners.

Dr. CHAMBERS supported the motion, and contended that the Society of Apothecaries ought to be continued because, among other reasons, it was the only English body to which women could go for diplomas to practise; the curriculum of the London University being unsuitable.

Dr. MCVAIL supported the motion for the appointment of examiners. He said that in that case the Council would become the examining body, and they could surely ensure that the examinations were sufficient. It was utterly absurd, therefore, to say that a number of inferior practitioners would be appointed. The Act of Parliament gave the Council no option whatever. It had been assumed that it was an Act which extinguished the Apothecaries' Society, and that the Council was appointed the executioner, but from the beginning to the end of the Act there was not a single word to support that notion. It might have been that the College of Surgeons found itself unable to give the full qualification, but was it to be said that therefore that College was to be extinguished? The past history of the Apothecaries' Society was very honourable, take it all in all. Undoubtedly here and there in the reports of visitation of examinations there might be found observations not of the most complimentary character on some part of the Apothecaries' Company's examinations, but that did not apply to that Company alone. He was sure that anyone acquainted with the medical practitioners of England would admit that the licentiates of the Apothecaries' Company had been as worthy members of the profession as those of any other body in the kingdom.

Dr. KIDD asked whether the Council was prepared to accept the responsibility of becoming an examining body. So far as he was concerned, he was not prepared to accept the responsibility. They were asked to set up an examining body under their own control, and that body was to be a competing body with the Colleges of Physicians and Surgeons. That was a position that was altogether contrary to the public welfare. If the amendment were carried, the effect would be simply to refer the matter to the Privy Council; and if the Privy Council decided that examiners must be appointed, it would take away the responsibility from the Medical Council.

Dr. HERON WATSON said that no sufficient reason had been advanced for refusing the crave of the Apothecaries' Society. He hoped it would not enter into the imagination of any of the members of Council, nor of the profession generally, that they were really establishing a new institute, setting up a new examination, and taking steps which should enable a new university to be created at Blackfriars; but he did most sincerely hope that the Council would grant the crave of the Apothecaries' Society, would give them what they required in the way of an additional examiner, and so enable this most useful, valuable, and ancient body to be perpetuated.

Dr. AQUILLA SMITH supported the amendment.

Mr. BRUDENELL CARTER, speaking in reply upon the question of statutory obligation, said he thought there was a moral obligation upon gentlemen who accepted a certain definite position, such as membership of that Council, to fulfil the statutory duty which that position imposed upon them, or to retire from their position. He referred to what took place in April last year when he formed one of a deputation from the Society of Apothecaries to Sir Lyon Playfair, the object being to point out that they did not think they were sufficiently protected by the words "think fit," which then carried no right of appeal. Sir Lyon Playfair, in his reply, stated that the clause was put in specially for the protection of the Apothecaries' Societies, because it was not thought desirable that those Societies should be extinguished. Stress had been laid upon the changes made in the statements in the medical journals with reference to the Society of Apothecaries. That change was only an indication that the Society had improved its position in the estimation of the profession.

The amendment was then put, as moved by Dr. Struthers, and was rejected by 19 votes against 9. One member of the Council did not vote, and two were absent.

The debate was then adjourned.

ABSTRACT OF

LECTURES ON MALARIAL FEVERS.[1]

BY W. NORTH, B.A., F.C.S.,

LATE RESEARCH SCHOLAR OF THE GROCERS' COMPANY.

LECTURE III.

RECENT RESEARCHES INTO THEIR ETIOLOGY AND PATHOLOGY.—THE POSSIBILITY OF PREVENTION IN THE INDIVIDUAL AND OF IMPROVING THE CONDITION OF MALARIOUS COUNTRIES.

AFTER considering the general and local distribution of malaria and the conditions under which it exists, the next question which arises is, How far may the symptoms which characterise the disease be regarded as the natural consequence of exposure of the individual to these conditions? Or is it necessary to go further, and seek their origin in some poison whose growth and development are especially fostered by these conditions. A simple uncomplicated attack of malarial fever, as is well known, begins with a "cold stage," often accompanied, but not necessarily, with more or less violent rigors; then follows a "hot stage," or condition of fever, which terminates in profuse sweating—the "sweating stage." It is possible for a patient to have such a train of symptoms, and to recover and have no return of them if he be promptly treated; but in most cases they repeat themselves at varying but exceedingly regular intervals, constituting what is known as quotidian, tertian, and quartan ague. Further, it is possible for an individual, after an interval of immunity varying from days to years, to have a recurrence of the symptoms, though not, as a rule, with the same period of intermission, and in old cases the regular intermission disappears. Further, these symptoms may, and often do, reappear under conditions which render it impossible that there should have been a fresh access of poison; and an individual who has once suffered appears to be more or less liable to returns of the disease as long as he lives; and should he be attacked by any febrile disorder whatsoever, a distinct intermission will generally be found added, as it were, to the ordinary symptoms of his disease, and this intermission will disappear under the treatment usually prescribed for ague—viz., the use of quinine, arsenic, and the like, in addition to any drugs proper to the treatment of the particular disorder from which he is suffering. If

[1] Delivered at the London Institution, April 28th, 1857.

Digitized by Google

ıtiperiodics be not administered, the intermission will sappear with the disease, and may not manifest itself ɡain until the patient suffers from some other disease. ɡain, in a person who has once had ague, an attack may ı provoked by a number of widely different circumances—e.g., fright, surgical injury, nervous and physical haustion, sudden chill, &c.; and not only will these circumances bring about an attack, but some of them are equally ficacious in cutting one short which has just begun. In ıe very grave forms of the disease known as "pernicious" ıe fever is often continuous and frequently fatal. These ses—in the Roman Campagna, at all events—are not very ımmon, and, in the author's opinion, are rarely, if ever, first" attacks; and though a first attack may be severe, ıere is a very large amount of evidence to show that interittent fever, except perhaps in the case of persons of very eble constitution, cannot be acquired by a few hours' posure in a malarious locality, and that there is some ırt of connexion between the duration of the exposure and ıe severity of the attack. This varies enormously in fferent individuals, and though it is exceedingly doubtful hether such a thing as absolute immunity exists, there e certainly such differences in susceptibility as to render at all events conceivable.

The pathological changes in the organs and tissues which ɔcompany the disease are somewhat obscure. In grave cases ıere is always a large amount of melanæmia, which manists itself in the liver, spleen, and kidneys, and especially ı the cortical substance of the brain, where the capillaries e found to be loaded with minute black granules. The ılenic trouble which is characteristic of most cases would ɐem to point to some special interference with or alterations ı the functions of that organ; and it is not surprising, ıerefore, to find in the blood evidence of profound changes ı the red corpuscles and their pigment, and the production certain amœba-like bodies, which, under the name of lasmodium malariæ, have been described by Drs. Celli and archiafava as the cause of the disease, the transmissibility which they claim to have proved by the intravenous inction of the blood of a patient suffering from intermittent ver into an individual who was said never to have had it in s life. It is needless to remark that the experiments are open very grave objections—so grave as to deprive the result almost all its significance. Dr. W. Osler has given a very ll account of these so-called "hæmatozoa of malaria" in the *ritish Medical Journal* of March 12th. Here it will suffice state that all attempts to discover an organism capable producing the disease in the air, soil, or water of malarious calities have signally failed, though a number of organisms ıve from time to time been announced as such; nor have ıe attempts to cultivate the blood of patients produced ıy better results. The experiments of Dr. Silvestrini on ıe subcutaneous injection of dew, water, and the water in hich soil from exceedingly malarious localities had been ashed, are interesting. Sixty-three experiments of this ind yielded absolutely negative results, and, despite the rge amount of work which has been done in the search r a pathogenic organism, a confirmation of the existence the peculiar changes in the blood above referred to presents the progress made; and proof that the disease has s origin in such an organism, or that the bodies discovered ı the blood come from without and are not the outcome of ıanges in the corpuscles themselves, is still wanting.

There is one other theory as to the cause of the disease hich claims serious attention. The so-called "chill theory," ɔcording to which the thermotaxic nervous system, in ıdeavouring to adapt itself to the needs of the body ɾposed to the great and violent changes of temperature ıid to occur in malarious countries, breaks down and ɔcomes disorganised; that is to say, malarial fever is essenally a disease of the nervous system caused by exposure to imatic conditions. "Chill" is probably a wrong term to ɐe; for the break-down is more likely to be occasioned by ɾposure to excessive heat than to excessive cold, and, cndering that we know practically nothing of what occurs ı the body when exposed to a temperature above its own, ıe theory cannot be summarily rejected. It depends, hower, on the supposed existence of these violent changes, hich have not apparently been made the subject of accurate ɔservation by those who have urged this explanation of the isease.

From a large number of experiments made by the author ı exceedingly unhealthy sites near Rome in the summer of 385, it would appear—1. That the daily range of temperature in these places is very great. 2. That the changes are sudden and violent. 3. That the characters of the curves indicating temperature and tension of aqueous vapour present in the atmosphere present most marked differences in localities barely 200 metres apart horizontally, and similarly marked differences are found in the records of instruments placed at different vertical heights above the soil. 4. The connexion between these variations of temperature and vapour tension and the malarious character of the localities in which they were observed is such as to lead to the conclusion that, if not in themselves the cause of the disease, they must directly affect any organism to which such a power could be attributed; and it would seem fair to conclude that if these climatic conditions could be modified, the pathogenic organism which may be supposed to thrive under them would disappear, and the localities in question become healthy. Either as a sufficient cause in themselves, or as controlling the growth of organisms, these phenomena undoubtedly have a most intimate connexion with the disease, and it becomes possible for us to understand the real value of the precautions universally deemed advisable in malarious countries: fire, food, and clothing; the avoidance of low, damp ground for camps; the building of huts on poles, residence in the top floors of houses, and the like. It is difficult to realise from mere figures what these climatic phenomena really are, but one night spent in the Campagna in August would suffice to convince the most sceptical of the necessity of protecting the body against them, and to realise the wretched condition of the great bulk of those who are most exposed: ill-fed and worse clothed, they have to resist all day long a temperature often 104° F. in the shade, and to sleep in a damp wretched hovel, in an atmosphere saturated with moisture and a temperature which just before dawn may have fallen to 38° or even 36°, to rise in three or four hours to 100° or even more. A healthy person exposed for some time in places where these conditions obtain, runs grave risk of acquiring an intermittent fever, and one who has already had the disease will readily relapse under them, and may be attacked by one of the very grave forms. In both cases the result may be attributed to access of poison; but the same explanation will hardly hold in cases of relapse from exposure to heat and cold in a non-malarious country, and after years of immunity. Either the organism, if such there be, has a wonderful power of lying dormant and of being recalled to activity by exceedingly diverse conditions, or the thermotaxic nervous system, having once been thrown out of gear, readily breaks down again under strain. The recurrence of attacks would seem to be, as it were, a vice rendered the more easy by practice; consequently the anticipation of them by drugs or other remedies is of great importance in treatment. Chronic cases in which all regular periodicity has been lost are notoriously obstinate, and difficult, if not impossible, of cure. Much may be done, however, in all cases by avoiding exposure to the above-mentioned extreme variations of temperature and the maintenance of "tone" in the nervous system.

The question of the cure of a malarious country resolves itself into the removal of the causes of these climatic extremes, and this in turn into perfect control over subsoil water. Drainage and the planting of suitable trees are the well-recognised methods of effecting this; and the care bestowed by the Romans on their woods, and the elaborate system of drainage which they constructed in the hills round Rome, would seem to indicate that they, at all events, realised the vast importance of these things. It is very evident from the facts that malarial fevers have a most intimate relation to the soil and to local climate. In the case of the Roman Campagna it has been possible to some extent to trace the spread and increase of the disease *pari passu* with the depopulation and neglect of the soil, and whether malaria be due to the direct influence of climatic conditions on the individual or to a pathogenic organism, there can be no reasonable doubt that these peculiar local conditions form an important factor in the problem of its causation—and not only of malaria, but probably of other diseases. The peculiar form of enteritis known as typho-malaria exhibits a similar relationship to the soil, and in England infantile diarrhœa shows a connexion hardly less striking. Our knowledge of the relations of soil and climate to disease is scanty and very general, and a careful study of these local conditions would probably tend to throw great light on much regarding them which is at present obscure or almost inexplicable.

UNIVERSITY OF LONDON: ANNUAL MEETING OF CONVOCATION.

THE annual meeting of Convocation of the University of London was held on Tuesday last, the 10th inst, Dr. Wood, the Chairman of Convocation, presiding. Mr. Henry E. Allen, LL.B., B.A., was re-elected Clerk of Convocation. The report of the Annual Committee was received on the motion of Mr. Howse. The report contained the reply of Her Majesty acceding to the petition of the University to grant it the privilege of addressing Her Majesty upon the Throne "upon the occasion of the completion of the fiftieth year of Her Majesty's reign, and upon all future occasions in like manner as is allowed to the Universities of Oxford and Cambridge." The Committee also reported that revised regulations for matriculation had been framed by the Senate, embodying many of the recommendations of Convocation. The steps taken with regard to the reconstitution of the University were stated and the report of the Special Committee of the Senate on the subject was appended. The Senate had approved of the adoption of a motto for the University in accordance with a resolution of Convocation, and had referred the consideration of its selection to the Committee on Examinations in Arts, Science, and Laws. The Annual Committee desired that the subject of the expenses of Convocation be again referred to them, and with respect to a resolution upon the regulations for the doctors' degrees, were not prepared to make any recommendation. The report mentioned with regret the death of Mr. William Shaen, and stated that the vacancy in the Senate occasioned by the death of Mr. George Busk had been filled by the Crown appointment of the Right Hon. A. J. Balfour, M.P.

On the motion of Dr. Weymouth, seconded by Mr. Spratling, B.Sc., it was resolved that the resolution of January 17th, 1887, in regard to the annual expenses of Convocation, be again referred to the Annual Committee for its further consideration.

Dr. Napier moved, and Mr. Mears seconded, the reception of the interim report of the Special Committee for the consideration of the regulations for the examinations for the degrees in Law.

Dr. S. P. Thompson moved, and Dr. Napier seconded, a resolution, which was to the effect that in the voting for graduates nominated by Convocation to serve on the Senate the vote of each member should be restricted to one candidate. It should be remembered that Convocation is required to submit three names to the Crown, and that it has been the custom for the choice to fall on the candidate who has received the largest number of votes. It was urged that under the present system the candidate thus chosen might not represent the actual majority. After much discussion, in which the resolution was opposed by Mr. Macdowall, Mr. Tyler, Mr. Osler (who believed the proposed change was *ultra vires*), Sir A. K. Rollitt, and others, and supported by Dr. Weymouth, Dr. Nesbitt, Dr. Colline, and others, the resolution was carried. A further resolution, to make the nominations in rotation from amongst the Faculties of Arts, Science, Laws, and Medicine, was moved by Dr. Thompson, and seconded by Sir A. K. Rollitt. At present the selection is made alternately from the combined Faculties of Arts and Laws and those of Science and Medicine; and it was urged that this gave a disproportionate representation on the Senate to graduates in the Faculties of Arts and Medicine. Sir Julian Goldsmid opposed the resolution, and in the course of his speech referred to the "inchoate scheme" for the reconstitution of the University now before the Senate, expressing his belief that it would be long before it emerged as a real fact. Several graduates spoke, and eventually the resolution was lost.

On the motion of Dr. O'Reilly, seconded by Mr. Enright, the meeting reaffirmed previous resolutions in favour of the establishment of London local examinations by the University; but a further resolution to initiate the undertaking by means of a voluntary Permanent Committee, or Syndicate, was passed over.

Mr. E. S. Weymouth, M.A., moved, and Mr. Nesbitt, M.A., seconded, a resolution that Convocation cannot assent to any scheme for the establishment of Faculties in which it will [illegible] representation [illegible] relating to a vote on [illegible]

The Annual Committee was appointed, the following members being elected:—

Faculties of Medicine and Science.—M. Baines, M.D.; A. W. Bennett, M.A., B.Sc.; W. L. Carpenter, B.A., B.Sc.; W. C. Coupland, M.A., B.Sc.; J. Curnow, M.D.; G. Eastes, M.B.; W. H. Holman, M.B.; H. G. Howse, M.S., M.B.; Sir P. Magnus, B.A., B.Sc.; H. Morris, M.A., M.B.; R. Neale, M.D.; M. F. O'Reilly, D.Sc.; W. J. Spratling, B.Sc.; F. Taylor, M.D.; S. P. Thompson, D.Sc., B.A.; W. C. Unwin, B.Sc.

Faculties of Arts and Laws.—J. B. Benson, LL.D., B.A.; J. W. Bone, B.A.; M. P. Christie, B.A.; J. Hennell, B.A.; R. W. Hinton, B.A.; B. Kisch, M.A., B.Sc.; W. G. Lemon, LL.B., B.A.; A. McDowall, B.A., B.Sc.; S. P. Moore, LL.B., B.A., B.Sc.; T. B. Napier, LL.D.; H. A. Nesbitt, M.A.; W. Paice, M.A.; G. A. Smith, M.A.; E. S. Weymouth, M.A.; R. F. Weymouth, D.Lit., M.A.; B. Whitehead, B.A.

WILLS OF MEDICAL MEN.

THE will and codicil of James Drummond, M.D., formerly of Glasgow, afterwards of Richmond, and late of 5, Great Cumberland-place, who died on Feb. 28th last, were proved on the 16th ult. by George Skene Keith, M.D., the acting executor, the value of the personal estate exceeding £52,000. The testator gives his furniture and effects to his spouse Mrs. Jemima Johnston or Drummond; and there are bequests in favour of his mother and sister. The residue of his real and personal estate he leaves upon trust for his wife for life or until she shall marry again, and then for his children.

The will of David Scott, M.D., late of 52, Camden-square, Camden-town, who died on March 7th last, was proved on the 18th ult. by Mrs. Emma Louisa Scott, the widow, James Hamilton Wylie and Alfred Charles Preston, the executors, the value of the personal estate amounting to over £31,000. The testator gives all his household furniture and effects and £1000 to his wife; £150 each to his executors, James Hamilton Wylie and Alfred Charles Preston, and £1500 upon trust for his son David Forest. The residue of his real and personal estate he leaves upon trust for his wife for life, and after her death to his said son absolutely.

The will of Robert Elliot, M.D., late of 93, Denmark-hill, Camberwell, who died on February 15th last, was proved on the 4th ult. by Mr. Norman Bruce Elliot, M.R.C.S., the son, and Major-General James Mansfield Nuttall, C.B., the executors, the value of the personal estate amounting to over £12,000. The testator bequeaths £25 to his executor, Major-General J. M. Nuttall, to purchase a walking-stick or other momento of him. The residue of his real and personal estate he gives to his son Norman Bruce and to his three daughters Janet, Caroline, and Charlotte Alice in equal shares.

The will of Robert Bryce Gilland, M.D., formerly of the Berks County Asylum, but late of Fayremeade, Sevenoaks, who died on March 8th last, was proved on the 7th ult. by John Bryce Gilland, William Taylor (physician), and William Taylor (farmer), the executors, the value of the personal estate being sworn over £6000. The testator after leaving sundry legacies to persons connected with the Berks County Asylum, leaves the residue of his real and personal estate to his sister Ann Wilding Taylor absolutely.

The will of Charles Hutton, M.D., late of 26, Lowndes-street, Belgrave-square, who died on March 27th last, was proved on the 19th ult. by Mrs. Henrietta Sophia Elizabeth Hutton, the widow, and the Rev. Edward Seymour, the executors. The testator gives all his real and personal estate to his wife absolutely.

The Scotch Confirmation, under seal of the commissariot of Lanarkshire, of the deed of settlement, with two codicils, of Ebenezer Watson, M.D., of Glasgow, who died on Dec. 4th last, granted to Mrs. Mary Ferrier Young or Watson, his widow, Mr. James Ebenezer Watson, the son, and Mr. James Ebenezer Watson and Mr. Thomas Watson, the cousins, the executors nominate, was resealed in London on the 2nd ult. at the value of the personal estate in England and Scotland amounting to over £12,000.

The following legacies have recently been left to hospitals and other medical institutions:—Miss Harriet Gunn Fordham, late of Melbourn, Bury, Cambridgeshire, £500 to Addenbrooke's Hospital, Cambridge; £300 to the Hospital Stanton Convalescent Home; £200 each to the Royston Cottage Hospital, and the Hospital for Children with Hip-Disease

Digitized by Google

Sevenoaks.—Mr. James Chapman, late of Warminster, Wilts, £250 each to the Warminster Cottage Hospital and the Salisbury Infirmary.—Mr. John Clark, formerly of 34, Marischal-street, Aberdeen, but late of 19, Royal York-crescent, Clifton, Bristol, £200 each to the Royal Infirmary of Aberdeen, and the Hospital for Persons labouring under Incurable Diseases, Aberdeen.—The Right Hon. Henry Edwyn Chandos, Earl of Chesterfield, J.P., D.L., late of Holme Lacy, Herefordshire, £100 to the Hereford Infirmary.—Mrs. Eliza Maria Beaumont, late of Kenwood-park, Sheffield, £100 each to the Sheffield General Infirmary and the Sheffield Public Hospital and Dispensary.—Mr. Stephen Ponder Kennard, J.P., D.L., late of 17, Kensington-palace-gardens, £300 to the West London Hospital, Hammersmith.—Mr. Benjamin Lancaster, late of Sunnyside, Bournemouth, £1000 to St. George's Hospital, Hyde-park-corner, £500 each to the Middlesex Hospital, King's College Hospital, the Consumption Hospital, Brompton, and the Home for Incurables, Putney.—Mr. Moses Lea, formerly of the Stock Exchange, and of 27, Clarendon-gardens, Maida-vale, but late of 58, Maryland-road, St. Peter's Park, £1000 to the London Hospital, Whitechapel, £500 each to the Jews' Hospital, Lower Norwood, the Royal Ophthalmic Infirmary, Moorfields, the Home for Incurables, Putney, and the Cancer Hospital, Brompton. The residue of his property is to be divided between the London Hospital, Whitechapel, and the Jews' Orphan Asylum, Tender Ground.—Mr. William Westley, late of 24, Regent-street, £100 each to the General Hospital and the Birmingham Dispensary; £200 to the Consumption Hospital, West Brompton.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5899 births and 3704 deaths were registered during the week ending May 7th. The annual rate of mortality in these towns, which had been 21·6 and 20·6 per 1000 in the preceding two weeks, rose again last week to 20·9. During the first five weeks of the current quarter the death-rate in these towns averaged 20·9 per 1000, and was 2·1 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 16·0 in Birkenhead, 16·7 in Bolton, 17·2 in Nottingham, and 17·5 in Hull. The rates in the other towns ranged upwards to 27·2 in Oldham, 27·8 in Huddersfield, 31·0 in Manchester, and 34·2 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 558 and 529 in the preceding two weeks, rose again last week to 548; they included 249 from measles, 160 from whooping-cough, 45 from scarlet fever, 39 from diarrhœa, 32 from diphtheria, 22 from "fever" (principally enteric), and only 1 from small-pox. The lowest death-rates from these zymotic diseases were recorded last week in Birkenhead and Wolverhampton; and the highest rates in Liverpool, Manchester, Salford, and Norwich. The greatest mortality from measles occurred in Liverpool, Manchester, Salford, and Norwich; and from whooping-cough in Bradford, Liverpool, Oldham, and Huddersfield. The 32 deaths from diphtheria in the twenty-eight towns included 20 in London and 2 in Liverpool. Small-pox caused 1 death in Cardiff, but not one in Greater London or in any of the twenty-six other large provincial towns. Only 5 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; one new case had been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 337 and 338 in the preceding two weeks, further rose last week to 348, but were 9 below the corrected average. The causes of 81, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Nottingham, Portsmouth, Brighton, and Wolverhampton. The largest proportions of uncertified deaths were registered in Sheffield, Halifax, Cardiff, and Newcastle-upon-Tyne.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·0 and 22·5 per 1000 in the preceding two weeks, declined to 21·2 in the week ending May 7th; this rate exceeded, however, by 0·3 the mean rate in the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 9·4 in Leith and 13·0 in Perth, to 23·9 in Aberdeen and 26·0 in Greenock. The 529 deaths in the eight towns last week showed a decline of 34 from the number in the previous week, and included 31 which were referred to whooping-cough, 25 to measles, 11 to diarrhœa, 2 to scarlet fever, 2 to diphtheria, 1 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 72 deaths resulted from these principal zymotic diseases, against 95 and 89 in the preceding two weeks. These 72 deaths were equal to an annual rate of 2·9 per 1000, which was 0·2 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 36 in each of the preceding three weeks, declined last week to 31, of which 13 occurred in Glasgow, 8 in Dundee, and 3 in Edinburgh, in Aberdeen, and in Greenock. The 25 deaths from measles showed a further decline of 2 from the numbers in recent weeks, and included 12 in Aberdeen, 9 in Glasgow, and 3 in Greenock. The 11 deaths attributed to diarrhœa showed an increase of 3 upon the low number in the previous week, but were one below the number in the corresponding week of last year. The fatal cases of scarlet fever further fell last week to 2, both of which occurred in Edinburgh. The 2 deaths from diphtheria, also showing a further decline from recent weekly numbers, were returned in Glasgow; and the single death from "fever," occurred in Edinburgh. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 126, 124, and 111 in the preceding three weeks, further declined last week to 106, and were 2 below the number in the corresponding week of last year. The causes of 57, or nearly 11 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 31·3 per 1000 in each of the preceding two weeks, rose to 36·6 in the week ending May 7th, and exceeded the rate in any previous week of this year. During the first five weeks of the current quarter the death-rate in the city averaged 32·7 per 1000, the mean rate during the same period being but 18·6 in London and 19·4 in Edinburgh. The 248 deaths in Dublin last week showed an increase of 36 upon the number returned in each of the previous two weeks; they included 6 which were referred to measles, 5 to "fever" (typhus, enteric, or simple), 5 to whooping-cough, 3 to scarlet fever, and not one to small-pox, diphtheria, or diarrhœa. Thus 19 deaths resulted from these principal zymotic diseases, against 19 and 24 in the preceding two weeks; they were equal to an annual rate of 2·8 per 1000, the rates from the same diseases being 2·7 in London and 1·8 in Edinburgh. The fatal cases of measles, which had been 6 and 11 in the preceding two weeks, declined again last week to 6; while the deaths referred to "fever," whooping-cough, and scarlet fever showed an increase upon recent weekly numbers. The deaths of infants were within one of the number in the previous week, while those of elderly persons showed a considerable increase. Seven inquest cases and 7 deaths from violence were registered; and 93, or considerably more than a third, of the deaths occurred in public institutions. The causes of 31, or more than 12 per cent., of the deaths registered during the week were not certified.

ROYAL INSTITUTION OF GREAT BRITAIN.—The annual meeting of this institution was held on the 2nd inst., Sir William Bowman, Bart., LL.D., F.R.S., manager and vice-president, in the chair. The annual report of the Committee of Visitors for the year 1886, testifying to the continued prosperity and efficient management of the institution, was read and adopted. The real and funded property now amounts to above £83,000, entirely derived from the contributions and donations of the members. Forty-eight new members had paid their admission fees, and sixty-three lectures and nineteen evening discourses had been delivered. The books and pamphlets presented in 1886 amounted to about 288 volumes, making, with 443 volumes (including periodicals bound) purchased by the managers, a total of 731 volumes added to the library in the year.

"Audi alteram partem."

THE RELATIVE RANK QUESTION.

To the Editors of THE LANCET.

SIRS,—I have no sympathy with those who have again roused a spirit of opposition in a department which craved only one thing—viz., to be let alone, and not subjected to constant changes, the reason for which they could not be expected to understand, but the effect of which their previous experience gave them every reason to apprehend. The recent change involved a meaningless contradiction; for if A is brought in relation to B in regard to rank and position, that necessarily involves relative rank, if the English language has any meaning. But if the authorities choose to be so foolish as to state, what is evidently not the case and cannot be the case, that relative rank is abolished, they can only mean that the use of this term is to be discontinued, the thing meant by it is and must remain, and the War Minister affirms emphatically and unequivocally that not only has no change been made in the rank and position of any medical officer, but, in deference to the representations of others about a dispute, the meaning of which he declared to be simply inexplicable after the deputations had laboured in vain to make it apparent to him, he has offered to secure the rank and position of medical officers as definitely and precisely as human language can make it, by expressly specifying that each grade in the medical service shall rank, not *with*, but *as* the substantive military rank with which it corresponds, in all and every respect within the sphere which circumscribes and defines the position, functions, and duties of the medical officer. To my mind the word "as" not only includes, but is distinctly a stronger and more satisfactory expression than either "with" or "equivalent to." It must be clearly understood that, as the medical service forms a necessary and integral part of the military machine, it must be provided for and adequately recognised and respected in every way. It would be undignified to ask less; it would be absurd, as well as undignified, to ask more. The professors in our medical universities and schools are told, however, that they must shut their doors upon a public medical service, and an enthusiastic opposition to it is invoked. To what end? To secure honorary rank in substitution for that which medical officers now have; and to get some distinctive combatant military title incorporated with the medical one—such as captain, major, colonel, general. I confidently appeal to the civil medical profession to do nothing of the kind; and I claim to represent the views and feelings of some of the very best men in the service—men proud of their profession and emulous of getting on in and by it, and not by grasping at military titles which would only render them ridiculous in the eyes of those who from a professional point of view had a right to them; men whose professional knowledge is recognised, and who have, in a quiet way, done much to merit consideration.

Is it possible that after about half a century's contention to prove that, as we shared all the dangers, risks, and hardships of combatant officers in the field, supplemented by others in which combatant officers had no share, we should have our due proportion of honours and rewards—of C.B.'s, V.C.'s, and so forth—we should now put forth a claim for *honorary* rank—a rank bestowed upon officers (we speak of them with all respect and esteem) whose duties are of a purely clerical kind, and may be from the beginning to the end of a campaign performed in an office far removed from all possible dangers of a fight, and all the hardships of actual field service? It seems a monstrous step backwards, which these very *military* medical officers are pressing on the authorities! The medical officer is, on the one hand, non-combatant in the sense that the colonel commanding a regiment or an officer commanding a field battery in action is combatant; but, on the other, he is surely not to be put in the same category and on the same platform as the officer indenting for rations or casting up a pay bill. A medical officer's rank is relative, and the relation to other ranks appears to be better defined now than it ever was before, in spite of the abolition of the form of words "relative rank," but the medical officers owe the War Office no thanks for the change. I have no sympathy with that small section of medical officers who are more military than the military themselves. If they think that they are to obtain greater respect—military or social—by the titular military distinctions of Captain, Colonel, and Major, they will only find themselves, and not unjustly, very much mistaken.

I have always understood that the sense of professional trust and honour was so elevated and keen that, to take an illustration, a physician would refuse to make an experiment on a condemned criminal in order to test the truth of any theory—such, for instance, as Koch's comma bacillus being the essential cause of cholera; he would urge that it was his function to save human life, not to destroy it. But now it seems that the highest aim of a doctor is to gain the titles and be confounded with the rank of those whose function it is to fight and destroy life. But if so much value be attached to military titles, it is natural to expect that the holders of them will in consequence despise and depreciate professional ones. What has been the main aim and object of the medical profession—civil and military—of late years but to be welded more closely together by ties of mutual sympathy, and of associated aims, as members of a common profession with common interests? The strenuous efforts now being made to obtain purely military rank and titles must tend to create a very strong impression that these are held to be altogether superior to those arising from professional and academic distinctions. Is that a wise, judicious, or dignified course to adopt?

Advocacy of a cause is one thing; a fair judgment and consistency another. The combatant officer is scarcely tempted into the ranks of the service by the emoluments it offers. Whether the view be right or wrong, wise or silly, still there it is; he values military rank for the power of command it confers and the social value he thinks it gives. Honorary military rank has been bestowed broadcast among other than purely combatant officers, and distinctly with the effect of diminishing the value of such titles. Would there be no ground for the combatant officer's jealousy and dislike to the presence of a Surgeon-Colonel drawing the much higher pay of a medical officer on the one hand, and usurping a purely distinctive military title on the other?

The medical officer is now master of his own household; he has the responsibility of all that concerns the sick and the hospital service, and he has the power to command obedience and enforce his behests within those limits. To secure respect from others you must extend it to those within their sphere of responsibility. If a combatant officer presumed to interfere or to give advice inside the limits of a senior surgeon's duties and responsibilities he would have to pay dearly for his temerity. Surely, with the indisputable rank granted him by Her Majesty's warrant, the medical officer should have no difficulty in maintaining his position and in obtaining that respect from officers of other departments to which he is professionally and socially entitled.

I am, Sirs, your obedient servant, A. M. D.

*** The above letter, which, it will be seen, is strongly confirmatory of the view expressed in our leading article this week, is from the pen of a distinguished medical officer on the retired list.—ED. L.

GASEOUS RECTAL INJECTION IN CONSUMPTION.

To the Editors of THE LANCET.

SIRS,—I have read with much pleasure Dr. Burney Yeo's interesting lecture on a new method of treatment of consumption by gaseous rectal injections. During the last winter I have applied this treatment in a few cases. At first I used the apparatus described by Dr. Burney Yeo in THE LANCET, but lately I have preferred another (Sehet's), in which the gas is allowed to pass directly into the rectum, the amount being regulated by a screw. The pumping of the gas is done away with. The apparatus works well, and the patient can carry on the treatment by himself after he has been taught how to use it. I have always prescribed the "Eaux Bonnes," being careful to exclude all bottles not containing a good supply of sulphuretted hydrogen. At the beginning of the treatment two litres were injected, gradually increasing to four, and after awhile this quantity was injected twice a day. In every case the gaseous

Digitized by Google

injections were well tolerated. They never gave rise to any local or general disturbance. They were very soon followed by a marked improvement in the general condition of the patient. He gained flesh, the appetite increased, the hectic lessened. In one case tubercular infiltration was progressing rapidly, attended by a high temperature. It ceased to invade the lungs a fortnight after the treatment had been commenced. The patient is progressing favourably. He is still making two gaseous injections daily. It is nearly three months now since he began them. On the other hand, in this as well as in other cases, the bacilli are as abundant as ever; the cough persists, and is, perhaps, more troublesome, a lessened expectoration being one of the consequences of the treatment. Some of the cases left Cannes before I was able to form an opinion as to the ultimate value of this new method, and altogethef my cases are too few for me to pass judgment on it one way or the other. I believe, however, that it has done some good, certainly no harm, and with Dr. Burney Yeo I would say that the remedy is worthy of a more extended trial, and that "something" may come out of it.

I am, Sirs, yours truly,

Cannes, April 25th, 1887. H. BLANC, M.D., F.R.C.P.

THE PULSE.

To the Editors of THE LANCET.

SIRS,—I have read Dr. Broadbent's lectures on the Pulse very carefully; but the good they would otherwise do me is largely lost owing to a somewhat lax phraseology. In the first place, we are told the pulse is not an expansion of the artery, but simply an increase of pressure. Now there are three typical variations in the calibre of an artery—a maximum calibre occurring at the top of the pulse, a minimum calibre at the end of the diastole, and a mean calibre somewhat midway between these, corresponding to the mean arterial pressure. If Dr. Broadbent denies that the mean calibre or the minimum calibre is converted into the maximum calibre during the pulse, of course he denies the existence of varying calibres at all; and this is apparently what he means, because his explanation of the pulse is consistent with this view. Instead of varying calibres, he substitutes flattening of the artery, to account for the pulse. I may not properly understand him, and am in doubt whether he means that an artery is only flattened by and during the pressure of the finger on it, or whether the natural condition of an artery during the diastole is one of more or less flattening. If the flattening only occurs when we press with our finger, then the pulse does not naturally exist, for take away the pressure of the finger and the pulse is non-existent. If, on the other hand, an artery is naturally flattened during the diastole, this is utterly inconsistent with that continuous pressure of the arteries on the blood which maintains the circulation during the diastole, for from the moment the cylindrical form is lost pressure is practically abolished. Then we are told that tension and distension are almost similar terms, and mean the same thing. I find, too, by reference to my dictionary, that distension is given as one of the meanings of tension, and that expansion and distension have the same meanings attached to them. Now, according to Dr. Broadbent, during the pulse the pressure is increased, but the expansion of the artery is not increased. If this is so, then the distension is not increased, neither is the tension; and this implies that Dr. Broadbent does not consider pressure and tension as one and the same thing. But, unfortunately, in other portions of his lectures he talks as if they were the same thing; and between these two views those parts of his lectures relating to arterial pressure are lost on me.

I remain, Sirs, yours obediently,

East Greenwich, April, 1887. W. NICHOLSON.

RAGS AS CARRIERS OF INFECTION.

To the Editors of THE LANCET.

SIRS,—I read the able article on the above subject which appeared in your issue of the 30th ult., and, with your permission, would point out that uncleaned rags are often employed for making the flock of the flock bed. In Australia there are many flock-bed manufactories, and I do not know of one in which the rags are washed or otherwise cleaned before their conversion into flock. I am told that in England "it does not pay" to do more than "shake out" the dirt adhering to the rags before putting them in the machine that converts them into that material which composes the soft beds of millions. Exceptions to this practice doubtless exist, but I think medical authority should be brought to bear upon flock-bed makers who neglect to cleanse the raw material upon which they start.

I am, Sirs, yours truly,

R. W. E. MACIVOR, F.I.C., F.R.G.S., &c.,

May, 1887. Late Member of the Central Board of Health, Victoria.

LIVERPOOL.

(From our own Correspondent.)

THE EYE AND EAR INFIRMARY.

THE report of the Eye and Ear Infirmary, just published, shows that in 1886 there were 6109 new eye cases and 2352 new ear cases treated; 68 cataract extractions were performed, in 18 of which irrigation by Mr. McKeown's method was employed. This plan finds increasing favour with the surgical staff in cases of sticky cortex. In a considerable number of unripe cataracts a preliminary iridectomy and artificial maturation by stroking the cornea has been found to give good results.

THE TOXTETH PARK CASE.

A chemical examination of the stomach of the deceased girl, and of such of its contents as could be obtained, was made by Mr. Edward Davies, F.C.S., of the Liverpool Royal Institution, but with a negative result, none of the mineral poisons being found, except a small quantity of bismuth which had been given medicinally. The inference, therefore, is that death resulted from natural causes.

THE CLINICAL STUDY OF SMALL-POX.

Dr. Hope, assistant medical officer of health, has been appointed by the City Council visiting physician at the Park-hill Hospital. This will afford facilities to the students of the Medical Faculty of the Liverpool University College to become conversant with small-pox in its various phases, Dr. Hope, who is the lecturer on hygiene, being most anxious that such opportunities should not be lost.

HOSPITAL SATURDAY.

The 7th inst. being Hospital Saturday, boxes and cages were freely displayed in all parts of the city. Out of over 1000 boxes only 112 have been returned, the contents of which amounted to £397. There is every prospect of the result being considerably in advance of that obtained last year.

Liverpool, May 10th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE JUBILEE EXHIBITION.

ON Saturday last I was, as your representative, privileged to a private view of our Industrial Exhibition, now all but complete, and we can, in the words of our local poet, Dr. Hodgkin, in his very fine opening ode—

"Upon a bleak Northumbrian moor
Behold a palace raised."

For palace it is, regarded either as to cost, extent, wealth, or variety of exhibits. Much as I was prepared to see wonders from the articles in our daily press, I must say that all my anticipations were far exceeded when in the building. First as to the site. It is in a park forming part of the Town Moor, and in the northern suburbs of our city. It is only one mile from the Central Station, tramcars passing the building at very short intervals. The space at the disposal of the Executive Committee covers thirty-one and a half acres, or a little in excess of that provided for the late exhibition at Edinburgh. There is thus provided ample room and verge enough, not merely for the exhibition, but for the show of the Royal Agricultural Society of England, which, for the third time in its history will be held in the month of July next in Newcastle. As regards the building, it is con-

Digitized by Google

structed upon the systems adopted at the exhibitions at South Kensington. It contains a theatre to seat 1500 persons, art galleries, machinery in motion, and an internal garden which covers two and a half acres, while around it runs a pleasant verandah giving shelter from the sun and rain. The band stand is surrounded by pleasant walks and well-arranged parterres. The exhibits are full of interest, and many have a special interest for our profession, which I shall notice in future letters.

NEW HOSPITAL FOR SUNDERLAND.

It is now more than four years ago since the pressing need of a new hospital for fever at Sunderland was pointed out in THE LANCET'S sanitary report on the borough, and it is only just now we read that a commencement is to be made by the laying of the foundation stone, which is fixed to take place next Saturday.

NEWCASTLE INFIRMARY.

At the last quarterly meeting of the infirmary, a gratifying report was read, showing that the income had increased and the expenditure diminished. Dr. Philipson moved the following resolution, which was carried unanimously: "That in consideration of the life governors, the annual subscribers, and weekly contributors having agreed to relinquish their privilege of recommending patients, with the object of making the hospital accessible to the public, Her Majesty the Queen be respectfully invited to allow the institution in the future to be designated the "Royal Infirmary." It is as well to say that it is to be hoped that the governors will not allow their zeal for economy in the management to extend so far as to deprive patients of any necessary comfort. That there is a tendency that way will be apparent when I mention that a governor took strong exception to the amount expended on aerated waters—about £12, I believe for the quarter; indeed, he went so far as to say aerated waters "were a great humbug," and asked why the patients were not given "cold water"; but if this governor had the misfortune to suffer from surgical fever, with irritability of the stomach, he would be in a better position to appreciate the value of aerated waters.

NEWCASTLE DISPENSARY.

A curious dispute took place at the late meeting of the special court of governors called for the purpose of electing a physician. I told you in my last letter that Dr. Beatley, the late resident physician, was the selected candidate, canvassing being prohibited. The chairman ruled that, there being only one name put forth by the Committee of Selection, the election could not take place. There was a good deal said about canvassing, and, although the letter of the rule may have been adhered to, it was plain that the spirit had been somewhat infringed. Candidates have not canvassed, but the governors have been influenced by friends, and of course the candidate who gets the most governors' influence is elected. As it was, the governors present held that, as there was only one name before them, there was no choice, and so the election was postponed.

TYNEMOUTH INFIRMARY.

At a meeting of the Building Committee of the Tynemouth Infirmary, held in the Town Hall, North Shields, on Friday last, the architect presented his plans for the new building, and it was decided to ask the Dowager Duchess of Northumberland to perform the ceremony of laying the foundation stone on the Queen's Jubilee day.

Newcastle-on-Tyne, May 9th.

EDINBURGH.

(From our own Correspondent.)

THE ROYAL COLLEGE OF PHYSICIANS.

CONSIDERABLE interest in Edinburgh has centred in the recent election of the representative of this College on the General Medical Council, in the room of the late Dr. Rutherford Haldane. The election of Dr. Batty Tuke has been to many a surprise, and it indicates clearly the direction in which public opinion is now gravitating amongst the Fellows. There can be little doubt that Dr. Tuke owes his election to something approaching a declaration of independence among the younger Fellows, and that his return shows a tendency to a new departure in the internal policy of the College. He has frequently identified himself with movements of a liberalising nature, and that he is the choice of a majority of the electors shows that such changes in the direction of the College procedure would be received with a large measure of satisfaction. In other respects also the College is to be congratulated on its choice, for Dr. Tuke is generally recognised as a man of exceptional ability in the conduct of affairs, and his wide popularity with the profession in Edinburgh can but react favourably in the interests of the corporation he now represents.

THE COLLEGE OF PHYSICIANS' LIBRARY AND LABORATORIES.

I have had occasion in previous letters to notice the splendid library equipments possessed by the College, and the generous terms on which it placed these advantages within the reach of medical men engaged in study and research. Of late a rule of the College has been rigorously insisted on that indicates a reactionary feeling on the part of the College Council. All applicants for the use of the library not possessing the privileges of Fellowship are now refused access to the books unless they are accompanied by a Fellow *in propriâ personâ*. This results in the exclusion of many of our most diligent workers from their only local sources of information on special points in medical literature, and the continuance of such a state of matters must react very disadvantageously upon the vitality of the Edinburgh school. This is not, as far as is known, the result of any abuse of the previous generosity of the College, but seems to have arisen from some increased sense of jealous proprietorship almost inconceivable in a leading medical corporate body. There are hopes that the College will recognise the widespread feeling now abroad on this subject, and will add the grace of liberality to the virtue of loyally maintaining the present effectiveness of its library. In respect to its new laboratories, the College merits the highest praise for its efforts towards creating a greater earnestness in original research. The laboratories are rapidly approaching completeness under the auspices of Dr. Woodhead, who has handsome provision supplied him for making the equipment of the institution complete in every respect. The tariff proposed in relation to work done is no less generous, as it is understood that medical men are to be accommodated as workers free of charge and with the ordinary laboratory necessities supplied at the expense of the institution. In a few weeks these well-furnished rooms will be open for the prosecution of research.

THE COUNCIL ASSESSORSHIP IN THE UNIVERSITY COURT.

On Tuesday the election of an assessor in the University Court was concluded, and resulted in the return of Dr. Heron Watson by a majority of 587 votes, in a gross poll of over 5000 in number.

Edinburgh, May 11th.

DUBLIN.

(From our own Correspondent.)

THE CARMICHAEL PRIZES.

A MEETING of the Royal College of Surgeons was held on Monday last to hear the awards of the judges (Messrs. Robert McDonnell, P. C. Smyley, and S. Chaplin) selected to adjudicate the Carmichael Prize Essay. Sir William Stokes, President of the College, who occupied the chair, said that however opinions might differ as regarded either the wisdom or the utility of the design of the founder of these prizes, yet it was satisfactory to learn that the great majority of the essays sent in possessed very considerable merit. More especially was this the case with the essay which had obtained the first place. It was a work of exceptional merit, and the judges had stated that it was one likely to be of great utility as a work of reference. The first prize has been awarded to Mr. Walter Rivington of London, for his essay on "Every Man is a Debtor to his Profession," and the second prize to Mr. T. Laffan, for his paper on "Aristides." It is a circumstance worth noting that on the last occasion when the Carmichael prizes were awarded both these successful essayists respectively obtained first and second prizes.

MEDICAL STUDENTS' ASSOCIATION.

A meeting of those interested took place at the Ledwich School of Medicine last week to consider the proposed

Digitized by Google

changes in connexion with the Conjoint Examination Scheme adopted last October by the Colleges of Surgeons and Physicians. After some discussion it was resolved to send a petition to both Colleges asking to be allowed to continue their studies according to the regulations under which they commenced their medical curriculum, making only such alteration in the final or qualifying examination as the Medical Act of 1886 required. It was pointed out that, in consequence of the uncertainty as to what might be required of them at the coming examinations in July and October, they would find it most difficult to give their minds to study, and that they feared it would be impossible to be prepared for the conjoint examination at such short notice should they have to enter for it. No postponement would get them over the difficulty, as school and hospital instruction would cease during the summer holidays. It has been arranged that a deputation of the students belonging to the Association shall wait on the Joint Committee of Management in reference to the matter.

ZYMOTIC DISEASES IN DUBLIN.

During the March quarter the number of deaths from zymotic diseases was 212, being 204, or 49 per cent., below the average for the corresponding quarter of the past ten years. As compared with the December quarter of last year, the deaths from scarlatina show a decrease of 44, fever of 8, and diarrhœa and dysentery of 61.

Dr. Ahearn has resigned the post of medical officer for Ballickmoyler and Newtown Dispensary; and his successor will be appointed on the 20th inst.

Dublin, May 10th.

ROYAL COLLEGE OF PHYSICIANS.

AT an extraordinary Comitia on the 12th inst., Sir W. Jenner, Bart., President, in the chair, the following gentlemen were admitted to the Fellowship:—Drs. G. Oliver, R. Cory, H. R. Crocker, F. Buzzard, C. J. Cullingworth, W. J. Mickle, G. A. Heron, and J. Anderson.

A memorial, signed by 270 medical officers and teachers in London hospitals and schools of medicine, in support of the proposal that the two Colleges should obtain powers to grant a degree in Medicine, was read. It was referred to the Committee of Delegates.

Notification was made through the Foreign Office that an International Congress on Hygiene would be held in Vienna in the month of September.

On the motion of Dr. C. T. Williams, seconded by Dr. Julius Pollock, it was resolved to hold a *conversazione* in the month of June.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council of the Royal College of Surgeons on Thursday last the Minutes of the extraordinary meeting of the Council were confirmed.

An address of congratulation to the Queen on the completion of the fiftieth year of her reign was read, approved, adopted, and entered on the Minutes, and directed to be sealed and presented in the proper quarter.

On the report of the Nomination Committee, Mr. Howard Marsh was elected an Examiner in Anatomy for the Membership, and Mr. Davies-Colley for the Fellowship.

Further memorials from Mr. B. Brian were presented, in opposition to that recently presented by Dr. Wilks.

The Council resolved not to appoint any separate Examiners in Medicine and Midwifery for the ensuing year, on the ground that by the Medical Act of 1886 the diploma of Member will not be registrable alone as a qualification for practice.

The following resolution was adopted, and referred to the Colleges' Land Committee for further consideration and report:—"That, in accordance with the proposals contained in the report of the Colleges' Land Committee dated the 13th of December, 1886, it be recommended to the Council, with respect to the report from the President, senior Vice-President, and Mr. Marshall, referred to the consideration of the Committee, that the Council do agree with the Royal College of Physicians that the vacant ground on the Embankment be occupied by buildings suitable for such scientific purposes as may hereafter be resolved upon."

The Council proceeded to the further consideration of the report dated April 2nd, 1887, from the committee of delegates of the Royal College of Physicians of London and the Royal College of Surgeons of England, on the question of the granting by the two Colleges of degrees in Medicine and Surgery. This report included a recommendation from the Committee of Delegates that the overtures made on the part of the Council of University College and King's College, London, that the four Colleges should confer with a view to obtaining powers to jointly get degrees in Arts, Science, and Medicine, should not be entertained; and it was agreed to take the necessary steps to petition the Crown to grant a new Charter to enable the two Colleges to give degrees in Medicine and Surgery.

A petition sent in by Mr. F. Treves addressed to the Presidents of the two Colleges, and signed by representatives of all the metropolitan schools, in favour of the grant by the two Colleges of degrees in Medicine and Surgery, was received (see page 997).

The usual resolutions with regard to the election of members of Council on July 7th at 2 P.M. were passed. The following are the retiring members of Council:—Mr. Hutchinson, Mr. John Wood, and Sir Spencer Wells.

It was agreed, on the motion of Mr. Heath, that an extraordinary meeting of the Council be held, to be called at such a time as the President shall determine, to consider the disposal of the Erasmus Wilson bequest.

Obituary.

WILSON FOX, M.D., F.R.C.P.L., F.R.S.

WILSON FOX was born at Wellington, in Somersetshire, on November 2nd, 1831. His family belonged to the Society of Friends, a large number of whom were more or less closely related to him. His early education was at Bruce-grove, Tottenham; but he became a student of University College, London, in 1847. He studied in the Faculty of Arts, and obtained his degree of B.A. in 1850; he then entered the Faculty of Medicine in the same College, and among other honours obtained the Fellowes' gold medal in 1853. He was clinical clerk and physician's assistant to Dr. Walshe. He took his degree of M.B. Lond. in 1854, obtaining honours in Medicine, and proceeded to the degree of M.D. in 1885. He then studied in Edinburgh, where he was resident in the Royal Infirmary for a year. After this he visited Paris and its medical schools, on his way to Vienna, where he remained for a year. Subsequently he went to Berlin, and for two years studied assiduously, under the guidance of Professor Virchow. It was here, under the personal direction of Virchow, that his great powers for anatomical investigation were educed, stimulated, and developed. While in Berlin he made an important observation with regard to the degeneration of the gastric glands, finding in them the same kind of change that had been described by others in the intimate structure of the kidney in Bright's disease. The results of this investigation were given after his return to this country.

Dr. Wilson Fox married, in 1859, Emily, daughter of Wesley Doyle, Esq., and not long afterwards was invited to accept the post of physician to the Royal Staffordshire Infirmary. This invitation he accepted, and at once entered upon a career of successful practice. His reason for going there was that the hospital presented a large field for continued medical and clinical research. After some time his health failed, and he came to London to be under medical care; but from this ill-health he entirely recovered, and returned to Staffordshire. In 1861, upon the strong recommendation of Professor Virchow, he was appointed Professor of Pathological Anatomy in University College, London, and not long afterwards assistant physician to University College Hospital. He was elected a Fellow of the Royal College of Physicians in 1866, and in 1867 physician to the hospital, Holme Professor of Clinical Medi-

Digitized by Google

cine, and also a Fellow of University College. He contributed a paper in 1866 to the Philosophical Transactions of the Royal Society on the "Development of Unstriated Muscular Fibre." In 1870 he was appointed Physician Extraordinary to the Queen, and became a Fellow of the Royal Society. Soon after the marriage of the Duke of Edinburgh Dr. Fox was appointed Physician in Ordinary to their Royal and Imperial Highnesses. A most important paper was published in the Transactions of the Royal Medical and Chirurgical Society on the "Origin, Structure, and Development of the Cystic Tumours of the Ovaries"; also a remarkable contribution to science in the *Medical and Chirurgical Review* on "Purpura," giving the details of a fatal case, accompanied by waxy degeneration of the muscles. In this paper he gave full evidence of his great power as a microscopical observer. He contributed also various papers to the Pathological Society, and was elected its vice-president, an office which he held from 1875 to 1877. At this time he became librarian of the Royal Medical and Chirurgical Society, and continued to perform the duties of that office until his death. In 1868 Dr. Wilson Fox delivered a lecture before the Royal College of Physicians on the Artificial Production of Tubercle in the Lower Animals, which was afterwards published in THE LANCET, and re-published in a separate form. This paper contained in clear and concise form the results of long-continued research, and was a most valuable addition to our knowledge of the etiology and pathology of tubercle. In 1871 Dr. Wilson Fox originated in this country the treatment of hyperpyrexia by cold affusions and baths, and, in spite of apparently the most obvious difficulties and dangers, carried his case through to a successful issue. He wrote the article on "Diseases of the Stomach" in "Reynolds' System of Medicine," which was subsequently re-published in a separate form. He contributed also to the same work the results of one of his most important researches in his exhaustive article on "Pneumonia."

At the Pathological Society, in 1873, Dr. Fox opened a discussion on the Anatomical Relations of Pulmonary Phthisis to Tubercle of the Lung, occupying the whole evening in a lucid exposition of the subject, founded chiefly on his own work, but taking cognisance of all that had been done by others, from Bayle to Niemeyer. Another important contribution to science was given by him to the Medical and Chirurgical Society about the same time, on the Temperature, Pulse, and Respiration in Phthisis and Acute Tuberculisation of the Lung, founded on eighty cases observed by himself in University College Hospital. At the meeting of the British Medical Association in Manchester (1877), he opened a discussion on the Mortality of Pleurisy considered in relation to the operation of paracentesis thoracis, accompanied by most careful tables of mortality from various sources. His great work on Diseases of the Lungs is not yet published, but, we believe, is almost complete. It has occupied him during the last fifteen or sixteen years, and is accompanied by an atlas containing his own microscopical drawings, and coloured plates, the latter produced under his most careful direction.

Dr. Wilson Fox's first wife died in 1870, leaving him with three sons and three daughters. In 1874 he married Evelyn, daughter of Sir Baldwin Wake Walker, Bart., widow of the late Captain Hugh Burgoyne, R.N., V.C., who survives him. We have already given an account in this journal of Dr. Fox's last illness, and of its sad termination at 4 A.M. on May 3rd, at Preston in Lancashire. The funeral took place at Taunton in Somersetshire, on Friday, the 6th inst., where several of his nearest relatives had been buried. Mrs. Wilson Fox and all his sons and daughters were present, with a number of relatives and friends. The Queen was represented by Dr. Russell Reynolds, Physician in Ordinary to Her Majesty's Household, who was entrusted with a wreath to be placed by him on the coffin on Her Majesty's behalf. Attached to the wreath was a card, on which Her Majesty had written the following words: "A mark of sincere regard and esteem from Victoria R." A very large number of most beautiful wreaths, crosses, and other tokens of affection were sent from sorrowing friends and relatives. They were placed in the chapel, and then around the grave. The service was read by the Rev. Henry Jones, M.A., hon. chaplain to the Queen, Prebendary of St. Paul's, an affectionate friend for many years, assisted by the Rev. F. Baggalay, M.A., son-in-law of Dr. Wilson Fox.

In this endeavour to give some slight sketch of Wilson Fox's life, which was so beautiful, and of his death, which was so sad, we feel that but scant justice has been done to the character of one so great and good; and we therefore add the impressions that were made on us through four years of intimate acquaintance and most loving friendship.

As a "student" Fox was industrious in his work and thorough in his play. He enjoyed both, and one as much as the other. In the class of Professor Malden, he entered into the mirth of Aristophanes with intense pleasure and amusement, and his keen sense of humour enhanced to him the delight of hearing the ancient Greek author's fun "done into English" by the staid and learned modern Professor. It was the same in the mathematical course, and in other classes in the Faculty of Arts; and when he commenced his career in the Faculty of Medicine he was a most diligent learner in the classes of Sharpey, Graham, and Quain; and, subsequently, in the hospital wards, under the direction of Walshe, Jenner, and Parkes. But, at the same time, he gave himself healthy recreation in walking, riding, cricket, racquets, and music; and during vacation days in mountain climbing, both in England and abroad. Work and play were duly balanced, and each helped the other, and each to him was a delight. He listened and observed eagerly, assimilated rapidly and yet thoroughly, so that he could readily reproduce his knowledge when called upon to do so.

As "physician to a hospital," in both Newcastle and University College Hospital, Dr. Wilson Fox exhibited the most admirable combination of qualities. He was painstaking to the very highest degree in his study of each individual patient. To him the sufferer was a "human being," and not only a "case" from which to learn, and so add his mite, as he regarded it, to the sum of human knowledge. He felt that he had something to "do" as well as something to "learn." It was "the man" he had to investigate and treat, and the obvious disease from which he suffered was but a part of him. He could quickly make a diagnosis of the immediate source of suffering, and as readily give relief where such was possible. But he was not content with any such routine work as that might be. He would trace disease as far as could be, to its source. He made it his business to know "the man" thoroughly, to grasp facts that the stethoscope could not reach, and, while searching into the morbid physical processes of every organ in the body, kept in view the heavy burden of the soul, which lay beneath and often was the source of the greatest suffering. This he did by inspiring utter confidence in his kindness, knowledge, sympathy, and power to help. These qualities rendered him to his hospital patients, as well as to others, the successful physician, the wise and steady counsellor, the beloved and trusted friend. His great success as a "teacher" depended upon the thoroughness of his knowledge of the thing he had to teach; his ready appreciation of the plane upon which his pupils were standing; his sympathy with them in their blameless ignorance, and in their desire to learn; his peculiar lucidity of expression; his rapidity of illustration by analogy; his versatility and humour; and, most of all, his earnestness. Whether in college theatre or at the bedside of patients, he would exhibit his mastery of the minutest details, but would, at the same time, bring his genius as a burning glass to gather all details to a focus, and place in the strongest light the primary and all important points that needed observation, study, and recollection. In thus concentrating the facts or dogmas with which he dealt, he achieved a double success, he presented the subject-matter of his lesson in the best form possible, and concentrated at the same time the attention of his pupils. The attention he had won by his skill he riveted by his enthusiasm. His teaching was of the highest moral tone, everywhere and at all times; and although he would most kindly give individual help to a dull student who was struggling to advance, he could give him, with all good grace, a sharp goad onwards; an idle and conceited man he would at once put in his proper place, and perhaps "treat with bitter banters"; but "a fool," although he would be generous to him, he could not abide. His pupils, now scattered far and wide, must be numbered by many hundreds, and there can be among them no one worthy of the name of student who will not sorrow deeply at the loss of him to whom they owe so much, nor fail to cherish with profound gratitude the memory of their teacher and their friend. On his dying bed he sent this message to his pupils: "Tell my boys, the students of University College, how much I love them. Tell them that the surest road to success is to have a high

Digitized by Google

ındard of right and honour, and to adhere strictly to it." is message was given to Dr. Arkle, a former pupil, for ıom he had a great regard, and for whom he had sent ıen becoming ill at Preston, and who watched him with voted attention to the last. It was communicated to the ıdents by Dr. Gowers, who enforced upon them the great ample that Dr. Fox had set before them.

In his capacity as a "worker in physiology," pathology, and ıdicine, Dr. Fox followed closely in the steps of the greatest vestigators of Nature's secrets. Their method was his—to ertain the facts by every means in his power, to see all at was to be seen, to read all that was written in the ok of Nature, and to "read between the lines" by stituting experiments, and so shifting the relations tween materials and forces, both inside and outside the ing organism, as to anticipate the results of slowly cumulated observations. His work was done in no ıdom way, but with distinct and careful forethought; recorded faithfully, step by step, the facts that lay before n; proving, and, indeed, almost over-proving, the conclu- ns to which he had arrived, advancing by a strict process induction, guided by acute selective faculty between the eat and small, the relevant and irrelevant, or collateral, til he was convinced of the accuracy of the answers ıture had given to his inquiries, and then, and not till en, placing them as truth before those who wished to ow how he had read her mysteries. His power of ob- rvation, innately good, had been sharpened to the finest, enest edge by his long-continued studies in England, otland, and Germany. He had great faculty for original vestigation, and an energy that was as untiring as it was tient. But beyond these qualities, which were his bitual working tools, he was endowed with undeviating votion to truth, and yet further with most buoyant hope. As an "author" Dr. Fox's great qualities found worthy pression, but only those who knew him intimately in his de of writing and of publishing can be aware of the great st and enormous amount of labour he imposed upon him- f in order to secure accuracy and fulness. Many years o it was said by a great author that "no man should ite a book unless he could put into it all that was own until his time, and so add to it that there could be thing to be said afterwards." In the line of work which Wilson Fox had adopted the latter term was an impos- ility, but in so far as there was possibility he secured the mer. His reading of all literature, past and present, that re upon his subject was wide, deep, and critical; and e pains which he took to verify quotations by one thor from another, whether in monograph, contribution to entific journals, in this country or elsewhere, was beyond praise. His work was so elaborated that sometimes fore he had reached the end of an article some fresh pers came forth from the teeming press of France, rmany, Italy, and America, and all that was worthy in ese he felt bound to digest and introduce. This marvellous lustry, while it has given the greatest value to already published works, has yet delayed the pro- ction of his "Magnum Opus," now nearly finished.

Regarded as a "member of the medical profession," he was profoundly interested in all that affected its welfare. "Order" d "Progress" were the watchwords of his life. He was nest to preserve what was right; eager to make that ter; to remove what was wrong or unhelpful; to widen d advance, by new methods and in every direction, its ge of usefulness; and to secure this end, by reduction of necessary work, and the addition of other modes of pro- lure which might, in his opinion, conduce to this end. enly critical, he was no mere critic, but was always full of gestion and constructive genius. Having once made up mind, he rarely swerved from his purpose, but maintained ground by considerate courtesy to those who differed m him; by absolute intrepidity and perseverance in ending all that he believed was right; and so he often ceeded by impressing upon those who heard him the con- tion of the entire sincerity of his heart and judgment, l also by the eloquence and impetuosity of his words, ich made many feel that, in spite of obstacles, all things re possible to him that believed.

In his dealing with private patients he was all that has n said about him as hospital physician; and there is little re to add. He was entirely unselfish, truthful, and ost infinitely tender. With their friends he was the ne; and if, sometimes, his eager, earnest look might have en the feeling that he was over-anxious, those who knew him best knew also it was the outcome of his heart's deep feeling—neither alarm nor even fear, but—the unconscious expression of his loving sympathy.

As a "man," Wilson Fox was a Christian gentleman in the best, fullest, and highest meaning of those words. He lived soberly, righteously, and godly. Careful in his living, for the sake of others and himself, he was righteous to all with whom he had to deal, and his motives came from the highest source; he was eminently a godly man. Free from sectarianism as he was free from cant, he took great interest in the Christian Association of his College, and often gave wise words of counsel to its members.

As a "friend," only those who knew him best and loved him most can feel how absolutely impossible it is to find, in the poverty of words, any adequate expression of their thankfulness for his life and their unspeakable sorrow at his death. Many will feel, as with tear-blinded eyes they read this slight attempt, or any others that may be written, to recount his life, and tell their grief that it has now been taken from their earnest gaze, the full meaning of our great poet, when he wrote—

> "I cannot see the features right,
> When on the gloom I strive to paint
> The face I know ....."

There are many, however, who will be consoled to know that a few hours before his death, Wilson Fox said, in reply to a question put to him by a member of his family, "My only prayer is 'Thy will be done.'"

On the next morning, when obviously and consciously dying, and after his eyes had been fixed for a few minutes on the angle of the room, and as some grey streaks of dawn were entering it, he said suddenly—"There is a great light, a great glare of light.....I feel so strange.....a glare of light. What is it, Reynolds?" The reply was—"It is the peace of God." He grasped his friend's hand firmly and said, "God bless you," and in a few minutes after this

> "His soul to Him who gave it rose,
> God led him to his long repose,
> His glorious rest.
> And though the warrior's sun has set,
> Its light shall linger round us yet,
> Bright, radiant, blest."

Yes, dear Wilson Fox has gone into that light in which he trusted all his life through; the light that knows nor cloud nor shadow. This world is greatly poorer, but the higher world is richer in receiving, with bright welcome, a soul so strong, so loving, so good, so tender, and so true.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentleman, having passed the necessary examinations for the diploma, was at an ordinary meeting of the Council on the 12th inst. admitted a Member of the College:

Mitchell, Richard Pryce, St. Mary's-square, Cardigan.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a recent meeting of the Court of Examiners the following gentleman was admitted a Fellow of the College:—

O'Brien, John William, Melbourne.

UNIVERSITY OF DUBLIN.—The following degrees were conferred last week by the Vice-Chancellor of the University:—

LICENTIATE IN MEDICINE.—Alfred Russell Darley.
BACHELOR IN SURGERY.—Armstrong Herbert Swiffte Todd.
BACHELOR IN MEDICINE.—Walter James Buchanan, Robert William Henry Jackson, Henry Simpson Lunn, William Moyle O'Connor, Perceval Cecil Ryan, Armstrong Swiffte Todd, and John Henry Du Bedat Whaite.
DOCTOR IN MEDICINE.—George Thomas Revington.

SOCIETY OF APOTHECARIES.—The following gentlemen, having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates entitling them to practise as Licentiates of the Society on May 5th:—

Jaques, John Warren, Tyndale-place, Islington.
Pott, Francis Henry, Cornwall-gardens.
Worrall, Charles Lloyd, Buckfield, Leominster.
Whicher, Alex. Hastings, Westcombe Park, Blackheath.
Weld, Octavius, London, Canada.
Wooldridge, Arthur Tylee, Winchester, Hants.

On the same day four others passed the Primary Examination, four the Surgical, and one for Assistant.

[The name of "Francis Forbes Lanyon Penno" was in-

Digitized by Google

advertently omitted in the list of candidates who passed their examinations on April 28th, and received certificates to practise.]

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—Mr. Edward Cullinan has been elected to the Natural Science Entrance Scholarship.

JERVIS-STREET HOSPITAL, DUBLIN. — This institution has received £500, being a bequest by the late Captain Geary.

PORTSMOUTH has spent nearly £150,000 in improving its drainage. The new works were inaugurated on the 9th inst., with a pomp and ceremonial befitting their magnitude.

PRINCELY DONATIONS.—Sir George Stephen and Sir Donald Smith have given $500,000 each to found a Royal Victoria Hospital for the sick and poor of Montreal, and that city gives a fine site for the buildings.

KING'S COLLEGE HOSPITAL.—On the 10th inst., Princess Louise opened a grand bazaar in King's College, Strand, in aid of the funds of this institution. The hospital, which was founded in 1839, relieves annually about 20,000 persons.

THE FRENCH HOSPITAL.—The Queen has graciously consented to be patron of the French Hospital and Dispensary, Leicester-place, Leicester-square, and has sent a handsome donation towards the building fund of the new hospital about to be erected on a site in Shaftesbury-avenue.

ANDERSON'S COLLEGE MEDICAL SCHOOL.—In connexion with the reconstitution of Anderson's College under the scheme of the Glasgow and West of Scotland Technical College, the Medical Faculty of Anderson's College will in future be carried on as a separate incorporation, under the title of "Anderson's College Medical School."

MEATH HOSPITAL, DUBLIN.—The following prizes were awarded at the termination of the winter session:—First Medical Prize: Harry P. Sloggett. Second Prize: William Bagot. First Senior Surgical Prize: Thos. Galavan. Second Prize: Alfred Bewley. First Junior Surgical Prize: Oliver L. Robinson. Second Prize: George Hepenstal and Ernest Hawthorne.

THE FREEMAN CONVALESCENT HOME, BATH. — At a meeting of the Royal United Hospital Committee, held last week, the Mayor (Alderman Murch) presiding, it was decided not to accept the responsibility of the management of the Convalescent Home on Lansdown, given by Mr. H. W. Freeman as a Jubilee gift, towards the endowment fund of which only £1700 has been collected.

THE Committee of the Liverpool City Hospital, Netherfield-road, have accepted a tender for the erection of a new administrative block, laundry, mortuary, and boundary walls, together with additions and alterations to the east pavilion, and the formation of a complete system of drainage for the whole site of the hospital, for the sum of £10,533.

INSTRUCTION TO VOLUNTEER MEDICAL OFFICERS.—A course of lectures to Volunteer medical officers is now being given by Dr. Walter Pearce at the headquarters of the Volunteer Medical Staff Corps. A lecture on Barrack and Camp Hygiene will be delivered in the Parkes Museum on Wednesday, May 25th, at 7.30 P.M. Dr. Farquharson, M.P., will take the chair.

GLASGOW UNIVERSITY CLUB, LONDON.—Sixty-five of the members of this Club, with their guests, dined together at the Holborn Restaurant on the evening of Friday, April 29th. Professor Gairdner of Glasgow was in the chair. Amongst those who spoke after dinner were the Marquis of Lothian, K.T., Lord Watson, Sir F. Sandford, K.C.B., Lieut.-General Sir A. Alison, Bart., K.C.B., Sir T. A. Colt, Bart., M.D., and Professor McCall Anderson, M.D. During the evening the chairman read a congratulatory telegram sent to the Club by Principal Caird on behalf of himself and the Chancellor and professors of the University of Glasgow. The Club now numbers over 120 members. The honorary secretaries are Dr. Heron, 57, Harley-street, W., and Mr. McIlraith, 3, Furnival's-inn, E.C.

LEITH HOSPITAL.—The series of improvements in this hospital, which have been in progress for some time, have now been completed, several wards having been added to the charity.

SMALL-POX IN JAMAICA.—According to the latest advices from Jamaica, the epidemic of small-pox which has prevailed on the island since March, 1886, shows but slight signs of abatement. Between March 13th and 27th last 330 cases occurred, of which 19 were fatal. Since the commencement of the epidemic there have been altogether 615 cases and 590 deaths, of which 1990 cases and 353 deaths were in Kingston.

THE SANITARY CONDITION OF WARSAW.—Hitherto the inhabitants of Warsaw have been drinking Vistula water drawn from where the river is polluted by the drainage of the town, and the sewage has been running through open gutters, with which the streets are lined on both sides emitting pestilential odours. Important water and sewage works, designed to rectify this intolerable condition of affairs, are now approaching completion.

THE HOSPITALS ASSOCIATION.—The annual general meeting of members and associates will be held at the rooms of the Society of Arts, John-street, Adelphi, on Wednesday the 18th inst., at 5 P.M., at which the President, Sir Andrew Clark, Bart., M.D., F.R.S., will preside. On the evening of the same day the Association will be held at the rooms of the Medical Society of London, at 8 P.M., when a paper will be read by Dr. Wm. Collier, on "The best means to prevent the Abuse of Hospital Charity."

THE SANITARY CONDITION OF POOLE.—On the 11th inst., a Local Government Board inquiry was held at Poole into the application of the Town Council for leave to borrow £3000 for the erection of public baths. The inspector ascertained that there was no system of sewerage in the town and expressed the opinion that the Local Government Board would not be justified in giving encouragement to the growth of an increasing town like Poole unless there were simultaneously carried out a thorough system of sewerage. The mayor expressed the opinion that the death-rate of the town would increase if a system of underground sewers were substituted for the present cesspool system.

MEDICAL NOTES IN PARLIAMENT.

The Lunacy Board of Scotland.

ON the 5th inst., in the House of Lords, the Marquis of Lothian presented a Bill restoring to the General Lunacy Board of Scotland power to alter, enlarge, or restrict, in such manner as may be necessary, the present lunacy districts in Scotland. The Bill was read a first time.

Smoke Nuisance Abatement (Metropolitan) Bill.

On the 9th inst. Lord Stratheden and Campbell formally moved the second reading of this Bill.—The Duke of Westminster, in supporting the second reading, referred to the action of their lordships in 1884, when the same Bill was carried on a division, and concluded by asking them to give a second reading to the Bill, on the ground that it would be conferring a boon on those who were constrained to pass the bulk of their lives in an atmosphere greatly contaminated by smoke.—Lord Mount-Temple commented upon what he termed the barbarous circumstance that in London one-half of the fuel used did not produce heat at all, but simply rose into the atmosphere, irritating our nostrils and throats and inflicting enormous injury on buildings and everything. The Bill was, he thought, provide better machinery than at present existed without at the same time, making any alteration in the law, and there was no reason to believe that the measure, so far as it went, was not a useful but a safe one.—The Marquis of Salisbury explained that the Government could not resist the second reading, but he hoped that the noble lord would allow sufficient time to elapse before the stage of Committee to enable the metropolitan authorities to take cognisance of the Bill.—The Bill was ultimately read a second time.

Cremation.

On the 10th inst., Lord Forbes moved for a return of the number of cremations that had taken place in England within the last five years and asked by what authority and under what regulations they were permitted.—The Marquis of Salisbury said that the Government would have been willing to give such a return if it had been in their power. It was impossible, however, for them to do so, because, cremation being a matter of individual discretion, and not an official proceeding, no records were kept, or at least none that were accessible to the Government.—The motion was withdrawn.

Ventilation of the Vote Office.

In the House of Commons on the 5th inst., in answer to Dr. Tanner, Mr. Plunket stated that he was afraid it was true that the Vote Office was inconveniently small, and that at times when much crowded the ventilation is not very good, but he had not heard that the existing arrangements have proved injurious to the health of the officials in that room. He feared there would be considerable difficulty in mending the matter.

Digitized by Google

but he would consult with Dr. Percy as to what could be done as to substituting electric for gas lighting. The difficulty was that the plant for the electric lighting was already strained to the utmost.

The Vaccination Acts.

On the 6th inst., Mr. Channing asked the Secretary for the Home Department whether his attention had been called to the circumstances attending a recent execution of a distress warrant on a person residing at Kettering for non-payment of a fine under the Vaccination Acts, and whether he would make some representation to the local bench of magistrates to prevent any similar occurrences.—Mr. Stuart Wortley said that he had received a report as to the circumstances of this distress, but would cause further inquiries to be made in the matter.

Pleuro-pneumonia in Dublin.

In answer to Sir J. Swinburne, Lord J. Manners said that Her Majesty's Government had not taken any steps to prevent the landing in Great Britain of cattle from any part of Ireland; but as a result of correspondence on the subject the Irish Government had passed an order with the object of preventing the exportation of animals from certain districts in or near Dublin in which pleuro-pneumonia was known to exist. The correspondence would be laid before Parliament.

Females Labour at Collieries.

On the 9th inst., in reply to Mr. W. M'Laren, Mr. Stuart Wortley stated that the Secretary of State would be pleased to receive a deputation of those opposed to the prohibition of labour by women and girls at the pit bank. He would undertake that discussion on the clauses of the Bill in committee should be postponed for a week, but would avail himself of the earliest opportunity to take the general discussion before going into committee.

Army Medical Officers.

In the House of Commons on Thursday, Dr. Clark asked the Secretary of State for War whether, considering the great dissatisfaction that exists amongst medical students and the medical profession generally at the abolition of relative rank, which dissatisfaction may seriously diminish the number of candidates for the Army Medical Service, he will advise Her Majesty to issue a Warrant conferring honorary rank on all medical officers, and place them at least in as good a position as the officers in the Commissariat, Ordnance, and Pay Departments.—Mr. Stanhope: I think I have told the House several times that the abolition of relative rank will in no way alter the position or status of any medical officer. I have no reason to suppose that these officers are desirous of being called by titles which dissociate them from their duties. —Mr. William Corbet asked the Secretary of State for War whether, in view of the proposed alterations in the new Warrant with reference to the medical department of the army, the same privileges as enjoyed at present by the Royal Engineers would be extended to medical officers, viz., "That an officer, placed on half-pay on account of ill-health incurred in and by the service, may reckon time on half-pay, not exceeding one year, towards promotion, towards voluntary retirement, and towards retired pay."—Mr. Stanhope: The general rule for all departmental offices is not to reckon time on half-pay towards promotion or retirement. Medical officers come under this rule, in common with officers of all other departments.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE PENGE CASE.

DR. L. FORBES WINSLOW writes to remind us that at the time when the petition respecting the convicts in what was known as the "Penge Mystery" was first sent in, previously to the commutation of the sentence of death, he also obtained and sent a petition signed by 500 members of the profession. Dr. Winslow desires that all those who signed his petition should now sign the one alluded to in our last issue by Dr. Bristowe.

Students.—Nothing is yet decided by the Council as to the recognition of American or foreign diplomas.

SERIOUS RESULT FROM UNINTENTIONAL INTRA-UTERINE MEDICATION.

To the Editors of THE LANCET.

SIRS,—Having read your account of the fatal result of intra-uterine medication related by Dr. Otto Engstrom, I thought perhaps a short account of a case which has just happened in my own practice might be interesting.

On March 8th I attended a lady with her first child. About the third day, the discharge being offensive and the temperature elevated, I ordered injection of Condy's fluid and gave quinine. In a few days the temperature and discharge were normal. Ten days after this I was suddenly called at 10 P.M., and found the patient almost in a state of collapse. Violent and incessant vomiting and diarrhœa. Temperature 102·6°. The following was her statement:—For the sake of comfort she had continued using the syringe at night; but on this occasion when she introduced the vaginal tube she experienced intense pain, which was increased by the injection. Shortly afterwards her condition became so alarming that I was summoned in haste. I found on examination the os somewhat patent and the uterus abnormally low. The injection was deeply coloured with ordinary blood. On the following day the sickness had abated; temperature 102°; no abdominal tenderness, but intense pain in the back, which lasted for two days. The uterus was tender on examination per vaginam. Two days after the temperature rose to 104·4°, with rigors and vomiting. The patient was almost pulseless, and apparently in a dying state. My friend, Dr. Moon, saw her with me at 11 A.M. Still no pain, the back pain having left. On the following day the temperature sank to 103°, the rigors had ceased, and only a feeling of nausea remained. The next day the temperature sank another degree, and the patient complained for the first time of pain in the left groin as far as the left ovary. The pain remained severe for two days; but the temperature sank gradually to normal, the patient improving daily. She is now (April 25th) able to change her room, eating well, but feeling and looking extremely weak. The treatment consisted mainly in the exhibition of quinine, opiates, and soothing applications when necessary.

I am, Sirs, yours truly,

West Norwood, S.E., April 25th, 1887. JOHN B. HARRIS, M.D.

LANGMORE DEFENCE FUND.

A SUM of about £90 is still required to settle the heavy bill of costs for legal expenses incurred by Dr. J. Wreford Langmore for his defence in the recent action unjustly brought against him, which he, indeed, gained completely, but the expense of which, in consequence of the bankruptcy of the plaintiff, falls upon Dr. Langmore. The committee in charge of the fund desire to close it soon, and will therefore thank all gentlemen wishing to subscribe to send their donations at once to Mr. George Eastes, M.B., 69, Connaught-street, Hyde Park-square, London, W.

THE DISPOSAL OF LONDON SEWAGE.

To the Editors of THE LANCET.

SIRS,—In your issue of April 30th there is a most valuable note relating to the proposed disposal of the sewage of the Thames district and of the Lea district at Barking Creek and Crossness. Sir Joseph Bazalgette, the engineer of the London Board of Works, seems to be quite satisfied with the present plan of the Board, which treats the sewage at these outfalls with chemicals in two underground reservoirs of about nine acres in extent at Barking, and of about the same extent at Crossness. The extension of the Barking reservoirs will, I hear, make the whole extent at that spot of underground reservoirs about twenty acres; and, what with chemicals and steamers to convey the chalk and iron salts and mineral constituents of the sludge down the river Thames, it is calculated that the interest of ten millions sterling will have to be annually met by the ratepayers of the metropolis. All this, too, will be totally useless, and will certainly have to be undone in a few years. Meanwhile, Paris, which took lessons from English sewage farms, and Berlin, which did the same, are both in possession of splendid sewage farms at Gennevilliers and round about Berlin. The latter city has purchased no less than 19,000 acres of land, and is thoroughly content with her experiment. All who understand the question will agree that the only real way of treating sewage with effect is the physiological plan of passing it through suitable soils, and allowing the organisms contained in all pervious soils to split up the urea into ammonia, the food for plants. If London sewage were conveyed, as proposed by Col. Jones and Mr. B. Denton, down below Tilbury, and then pumped up on the lands of Essex, enormous amounts of rye grass and roots might be raised, and the Thames thoroughly purified.

I am, Sirs, your obedient servant,

London, May 3rd, 1887. C. R. DRYSDALE, M.D.

PROFESSIONAL ATTENDANCE ON SCHOOL BOYS.

H. B. W.—The rate of remuneration for professional attendance on boys at school varies very much in the same degree as attendance on the different grades of society. At Winchester the medical officers, two in number, are paid at the rate of two guineas per head. At Rugby the medical officer, who has sole charge of the school, is remunerated at the rate of about a guinea and a half per head. At Wellington College, Charter-house, and some other schools of the same class, the medical attendant receives one guinea for each boy. At Eton the older system prevails of remunerating the medical attendant after the manner of family practice. Each house-master selects his own medical attendant, whose remuneration is on a scale similar to that in family practice. The same rule is observed at the majority of grammar schools, as well as at most private boys' schools and girls' schools. The fee varies with the class of school—from five to seven shillings a visit. It would be better for all schools to follow the example of the higher grade public schools, and pay a sum per head for medical attendance, either inclusive or exclusive of necessary medicines. It occasionally falls very hard on parents who are struggling to give their children the best education their means will afford to have to meet a heavy doctor's bill as an extra to the school charges, whereas a guinea a year divided into three payments of seven shillings each school term would be an easy matter. Medical men would, as a rule, be found willing to attend schools at this rate where masters and parents were not needlessly exacting, which, as a rule, they would not be.

Mr. Thomas Laffan is referred to an article in our present issue.

Mytton.—No.

DR. RICHARDSON'S ELECTION FUND.

To the Editors of THE LANCET.

SIRS,—May I ask you kindly to inform your readers that the above fund was closed on April 23rd, and the audit published. I have since received two subscriptions (one to-day), which I have returned with a note of explanation; but as this involves trouble your insertion of this letter will oblige.—I remain, Sirs, yours truly,

FREDK. H. ALDERSON, M.D., Hon. Treasurer.

Hammersmith, May 4th, 1887.

SUICIDE IN ANCIENT ROME.

THIS sombre, though fascinating, theme has usually been handled as if a series of anecdotes of celebrated suicides sufficed to exhaust its interest; but Dr. Iginio Gentile of Milan, in an able memoir recently read before the Circolo Filologico of that city, adopts the more scientific method of treating it in relation to the notions of death, as these have been developed and embodied in the various philosophic systems. Aristippus of Cyrene proclaimed the nullity of existence, and sought to deprive death of its traditional horrors; and Hegesias, by persuading the Greeks that the sum of pain exceeds the sum of pleasure, caused so many to destroy themselves that his "prælections" were prohibited. Epicurus, shrinking from absolute pessimism, maintained that the dread was as culpable as the desire of death, which, by itself being neither a good nor an evil, might yet become, according to circumstances, either the one or the other. The next step in the evolution of the notion of death was that of the Stoics represented by Zeno, who placed the chief good in the pure repose of the reason, and limited himself to considering death as a necessary evil, and suicide as a rational mode of exit. These notions in the march of historical development penetrating the Roman mind, so averse to philosophical speculation, formed part of the groundwork of morals; and, in spite of the protest of the older citizens, who hated this intrusion of Greek subtleties, suicide received its sanction in the Latin "mori licet cui vivere non placet" (he is at liberty to die who does not like to live); so that self-destruction became common in the last years of the Roman Republic and in the first of the Empire—a period prolific in social and political perturbations. When the Empire reached its culmination, while there were development and vigour in the provinces, there were corruption and decay in the City, where the new condition of things supplied new incentives to suicide, and voluntary death, refined into a philosophy, became the crown of the career of the Roman voluptuary. It was in the upper classes, the old Republican oligarchs, become effete under the Empire, that this notion prevailed; but in the lower strata of society, in the suffering masses, germinated the mystic idealism that prepared the victory for advancing Christianity. Epictetus and Marcus Aurelius represented the last phase of philosophy which sanctioned voluntary death in a mitigated form, while the "acta urbis" (the daily journals) registered suicides every twenty-four hours. At last came the message of salvation, the new faith which preached the comforting doctrine of man's duty to live. Dr. Gentile's paper, highly interesting to its Milanese audience, may prove not less so to a yet wider public.

THE HONOURS REGULATIONS AT THE LONDON UNIVERSITY.

To the Editors of THE LANCET.

SIRS,—As an intending candidate for the 1st M.B. of London, might I be allowed to express a student's views on the recent honours regulations? I quite understand the reason of them—viz., to prevent every man who obtains a pass trying for honours in every subject on "spec," which I believe used to be a favourite amusement. This certainly ought to be stopped, as it simply meant extra and unnecessary trouble to the examiner. But the regulations do more than that; they prevent men trying for honours, and tempt men to read for the lower standard. Could not this be obviated by the following method? Make each candidate take the pass in each subject, and then if he obtains a sufficient percentage in any subject, let him have the option of trying for honours in that subject. The same regulations might also apply to the preliminary scientific. This method would effect a weeding out, and thereby enable the honours papers to contain purely honours questions—raising the standard. As it is, failure to obtain honours means possibly a recommendation for a pass, possibly failure. This would entail a heavy loss of time and money, that in most cases can be ill afforded, whilst at the same time there would be the irritation of feeling that one might not have failed if one had been more modest, whence would come the obvious moral—Don't read for honours again. Enclosing my card,

I am, Sirs, yours obediently,

May 9th, 1887. X. Y. Z.

REGULATION OF MINIMUM FEES.

Mr. Albert S. Morton complains severely of the low fees charged by some medical men, and of the system at Guy's and other hospitals of charging out-patients a small pittance, and taking, and even advertising for, in-patients at a guinea a week. Unless cases are carefully selected, such conditions might easily operate injuriously on patients and on the profession. But it is of little use to expect the Medical Council to regulate fees. Its business is to regulate medical education. Medical men themselves, and amongst themselves, must regulate fees; and the sooner it is understood that there is no power in any existing body or authority to fix fees or prescribe scales of charges the better. Our correspondent encloses a small circular advertising a cheap medical practitioner (M.D. St. Andrews and M.R.C.S. Eng.). He should forward this circular to the bodies from whom the gentleman in question holds his diplomas.

Student should write to the Secretary of the College.

ABSTRACT OF A

Clinical Lecture

ON

GUNSHOT WOUNDS OF THE EYE.

By CHRISTOPHER S. JEAFFRESON,

SENIOR SURGEON TO THE NORTHUMBERLAND, DURHAM, AND NEWCASTLE INFIRMARY FOR DISEASES OF THE EYE.

GENTLEMEN,—We have now for another year entered upon that season when the frequent use of firearms for sporting purposes brings its almost inevitable crop of accidents. Indeed, so common are these becoming that it is rare for the shooting season to pass without several such cases coming under my notice. Within the last few days my advice has been sought in two instances of this kind of injury. I am quite certain that these casualties are now much more frequent than they used to be, and we must look for the reason to several different circumstances. In the first place, there are many more sporting men, or, I should perhaps say, men given to sporting proclivities, than there used to be. Of these, many only take to the gun late in life, when the accumulation of sufficient means enables them to indulge in pastimes to which they have never been trained, but which for the sake of fashion they feel called upon to pursue. These patrons of sport, however careful they may try to be, are always dangerous companions upon a moor or in a cover. They always handle their weapons badly, are bad judges of distance, and lack that calmness and deliberation which are only acquired by a training commenced in early youth. Unquestionably, too, the use of breech-loaders has engendered a very rapid system of firing, which encourages recklessness in young and excitable sportsmen; and, finally, the system of grouse, and of late years partridge, driving is responsible for no small number of the casualties which occur. Not infrequently the butts are much closer together than there is any necessity for, they are not uncommonly very deficiently constructed, and the rules with regard to lateral firing are not sufficiently impressed upon each sportsman before the shooting commences. I find I have altogether notes of twenty-three cases of gunshot wounds of the eyes and orbital regions; to give them in detail would, however, occupy too much of your time and space. I shall therefore only refer to them when necessary to illustrate certain points relative to symptoms, diagnosis, and treatment. And here I may say that it is my intention in this lecture to confine my remarks chiefly to those injuries which affect the globe, reserving for another occasion the more severe form of injuries, where the globe is destroyed together with parts of the orbit.

Gunshot wounds of the eye do not differ very materially from injuries to the eyes which occur from the projection with force of particles of metal or other materials used in the arts and manufactures, but they are usually attended with much more shock. Sometimes this is peculiarly marked. Though the globe may have been only penetrated, or perhaps even only struck by a single pellet, the collapse may be as severe as when a bullet has entered one of the principal cavities of the body. On one occasion I was present when a young gentleman was struck by a spent shot on the globe; he immediately fainted, the faint being accompanied by general convulsions. His restoration to consciousness was twice within an hour followed by similar attacks. An examination of the eye showed only a slight abrasion of the cornea, and at the end of forty-eight hours his general health and the eye were completely restored. No doubt mental influences play a great part in this form of shock. The uncertainty of what has really happened, the forebodings of future sufferings, and the exaggerated fears of sudden and perpetual blindness acting upon a person of a sensitive and highly nervous temperament are enough to account for this condition. Although not infrequently several pellets strike different parts of the body at the time the patient is injured, still it happens with remarkable frequency that the globe is the only part struck. Indeed, so often does this happen that there is a popular superstition among keepers and persons of that class that the globe of the eye possesses a power of drawing a shot out of its course.

Shots may be "direct" or "ricochet." Ricochet shots may take place at the most peculiar angles, and the possibility of a double ricochet must not be forgotten. It is only by taking them into consideration that we can account for some cases in which the person wounded was in a position where it seemed almost an impossibility that he could be hit. Ricochet shots are, for a given velocity, much more dangerous than direct ones, for the following reason: Their primary impact usually destroys their spherical form, flattening them, and giving them an edge in some cases almost as sharp as a knife, and which peculiarly facilitates their penetration under a comparatively low velocity. The effects produced by the impact of a pellet upon the globe will naturally vary with the velocity of the shot and the angle at which it strikes, partly also upon the varying thickness and resistance of the ocular tissues in different individuals. The cornea is much less resistant than the sclerotic, and may be penetrated at a greater distance than the latter. From experiments I have conducted I think the penetration of the globe through the sclerotic is rare at a greater distance than seventy yards, although in the case of the cornea I believe it may occur up to eighty or ninety yards; and in one case where a No. 5 shot penetrated at the cornео-scleral junction, I was informed the distance of the injured person from the gun was fully 100 yards. For convenience sake we may divide these injuries into "non-penetrating" and "penetrating" wounds. The former may vary from trivial ecchymoses of the conjunctiva, almost unattended with visual disturbance, to extensive extravasations, subconjunctival and intraocular, with detachments of the retina, rupture of the choroid, and partial or complete displacement of the lens. On one occasion I found a shot in the superior conjunctival cul-de-sac; it had evidently struck the upper part of the sclerotic at one angle and glided under the lid.

In some cases there may be a momentary difficulty in assuring oneself if the globe has been penetrated—a difficulty which may be considerably increased if the patient is not seen till some days after the accident and the wound lies in the equatorial regions of the eye, away from the plane of the iris. The little wound, if it existed, may then have healed, or its site may be masked by chemosis or extravasated blood. It is usually to be found if diligently sought for. In these doubtful cases it is well to carefully examine the tension of the globe. A perforated globe generally shews a very marked diminution of tension compared with the healthy eye. When the globe has been penetrated more anteriorly the wound is usually sufficiently obvious, the iris being irregular or displaced, and in many instances partially prolapsing, and the lens is seen to be opaque and swollen. In other cases the whole of the deeper structures may be concealed by hæmorrhage into the anterior chamber. In doubtful cases we should never omit to call in to our aid all the points bearing upon the case, and we should make a detailed and minute examination into the circumstances of the accident, having fully explained to us the relative position and distances of the parties engaged. The elasticity of the sclerotic is such that the aperture made by a No. 6 shot may sometimes require a good deal of searching for. On one occasion, after the enucleation of a globe which had a most distinct and well-marked aperture of entrance through the cornea, immediate dissection of the eye failed to find any shot in the interior. This was very puzzling. After a very minute and careful examination the aperture of exit was found close to the inner side of the optic nerve entrance, the shot having completely traversed the globe. On examining the wound carefully, the pellet was found in close apposition to the cut extremity of the nerve and removed. A very oblique shot striking a very prominent eye may traverse it without lodging. There will then be the appearance of two apertures, which might mislead the surgeon into supposing that two shots had penetrated instead of one. Again, there may be but one aperture in the globe, and two shots may have entered, one following exactly in the footsteps of the other. Such a case occurred in my practice some years ago. The case is vividly impressed upon my mind from a curious coincidence.

A surgeon brought me a gentleman who had summoned him on account of a gunshot wound of his right eye. He was of opinion that a shot had penetrated and lodged

Digitized by Google

whilst another medical practitioner held a contrary opinion, and I was asked to determine the point. Upon examination it was decided that the globe should be enucleated, and I promised at a subsequent time to give the result of the dissection of the eye after it had been prepared by hardening in Muller's solution. In a fortnight both gentlemen appeared, and were equally anxious to learn my conclusions. Mr. A. said, "Well, was I not right—there was a shot in the eye?" I replied, "No." "Then," said Mr. B., "it was just as I expected—there was no shot in the globe." When I replied that he also was wrong, they both looked at each other with astonishment. They then pressed me for an explanation of this apparent inconsistency, and were much amused when I explained to them they were both wrong, because there were two shots lodged in the injured organ.

It may seem somewhat paradoxical to say that a shot may penetrate the globe without there being any visible aperture or external manifestation of the occurrence. Yet the possibility of this accident and its absolute fulfilment are amply illustrated by a case which I shall relate, in which it is more than probable that a considerable number of shot entered the posterior part of the orbit through the pterygo-maxillary fossa, producing blindness. The case, which was a most interesting one from many points of view, happened as follows:—

A number of gentlemen out shooting were walking in single file along the bank of a river, when a duck rose in front of them. The leading sportsman put up his gun to fire, as did also the one immediately behind him, and in the excitement of the moment the latter discharged his piece. The distance of the leading man could scarcely have exceeded five feet from the one immediately behind him, and the greater part of the charge from the latter's gun entered the right side of the foremost gentleman's head and shoulder. He fell as though dead, and was promptly removed to a neighbouring house. When I saw him some hours after the accident he was in the following condition. He was much collapsed from hæmorrhage and shock, but was sensible, and there was no paralysis. The right temporal bone was riddled by shot, and considerable hæmorrhage was still going on from these apertures; the ear was much torn and lacerated. The integuments over the temporal muscle were ploughed into furrows, and the substance of the muscle was a mere bag of ecchymosed blood and shot corns. Several shots had completely traversed the base of the skull, and, flattening themselves against the back of the teeth, had been spat out of the mouth. The right eye was deeply ecchymosed and somewhat prominent. With a little difficulty I was able to make a very satisfactory ophthalmoscopic examination. The media were clear and perfectly transparent, but the retina was covered with large hæmorrhagic patches. These were particularly visible upon the temporal side. Vision was completely abolished, with the exception of slight perception of light in the temporal half of the field; the nasal half of the retina having evidently escaped with less injury. I show you here, gentlemen, an enlarged rough sketch which I took of the fundus at the time, and I think there can be no doubt that these ecchymosed patches are the result of the impact of shot which arrived at the back part of the globe through the pterygo-maxillary fossa. The case proved a tedious and anxious one. During the course of treatment something like 150 shot were removed from the face and shoulder-joint, but a large number, in spite of extensive suppuration, must have remained lodged in the mastoid portion of the temporal bone. Sight, it is needless to say, was permanently lost in the right eye, but in other respects a perfect recovery took place without much visible disfigurement.

I previously mentioned incidentally the possibility of a shot traversing completely the globe, and lodging eventually in the deeper structures of the orbit. I may say that this is by no means a very uncommon result, and I have met with it on several occasions. Such an eye can rarely recover any useful degree of vision, but it may nevertheless recover very rapidly from the injury, and may thus belie the anticipations formed, and perhaps expressed to friends and relatives, of severe symptoms and prolonged suffering, which may have been legitimately urged in justification of enucleation. When a distinct aperture of entry is found in the globe, and on removing the damaged organ no shot is to be found in its interior, we should always suspect that the globe has been completely traversed, and make a minute examination for the aperture of exit, which is sometimes very difficult to see, and, if there is time, may possibly have closed. The shot, too, should be sought for amongst the orbital tissues, bearing in mind the fact that it may be wiped away in the sponges, these should be carefully looked after. Whether, however, the shot be found or not is not a matter, surgically speaking, of great importance, as it rarely gives rise to any mischief when left in the orbital tissues. Nevertheless, the patient and his friends never seem perfectly satisfied unless it is produced.

What is the treatment we should adopt in cases of gunshot wounds of the eye? Of course this will very much depend upon the nature and extent of the injury. In cases where there has been no penetration and the injury consists of ecchymosis of the conjunctiva with extravasation to a greater or less extent into the anterior or posterior chamber, we must use cold and evaporating lotions and do our utmost to guard against all inflammatory reaction. We shall usually succeed in this with young and healthy persons and in persons of more advanced years if there is an absence of gouty, rheumatic, or other diathesis predisposing to inflammation. In course of time the blood effused will be absorbed, and if the media regain their transparency and there has been no detachment of the retina, sight may eventually be restored to a useful degree. Are there any external or internal remedies which promote the absorption of extravasated blood? I must confess personally I have not much faith in any, but I usually order locally a weak lotion of lead and opium or belladonna, or, in cases where inflammation threatens, conium; and internally administer small doses of iodide of potass with tincture of jaborandi. I have more faith in this drug than any other, and certainly think its administration either internally or by means of subcutaneous injections in the shape of pilocarpine promotes absorption.

In cases where a shot corn has penetrated the globe the case at once assumes a more serious aspect and requires more radical measures. I must here only mention to condemn any attempts being made by probes or otherwise to search for the position of the shot or ascertain its presence. I have seen such attempts practised, but they can lead to no good, and may be productive of much harm by increasing the risk of panophthalmitis and suppurative inflammation. There is only one condition, or rather combination of circumstances, under which I should consider such attempts justifiable (and then only when we had reason to suppose the shot was close to the wound): that is, when the patient has already from some other cause lost the sight of the uninjured eye, or it suffers from such an amount of amblyopia as to render it practically useless. Under these circumstances we can be influenced by no fear of sympathetic mischief being developed, and every attempt should be made, and at all risk, to preserve the damaged organ if it retains nothing more than a mere perception of light. This rule applies, I need scarcely say, with equal force to accidents occurring from other mechanical causes than gunshot wounds. I have known enucleation recommended, and in more than one instance performed, before it was ascertained that the remaining eye was a useless organ, and I cannot too strongly impress upon you the necessity of making strict inquiry before you recommend such a proceeding. I have only once succeeded in extracting a shot from a wounded eye. On that occasion there was evidence of penetration about three inches outside the lowest part of the sclero-corneal junction, and a large piece of iris was protruding. The anterior chamber was full of blood, and there was no perception of light. The sight of the other eye was perfect. I recommended that the damaged organ should be enucleated; but the patient refused, and I therefore excised the protruding piece of iris. When I had cut it close off, a small black spot seemed still to project at the wound. Touching it with the iris forceps, I found it to be a shot. I slightly enlarged the wound and at once removed it. The patient recovered, but with no useful vision.

The enlargement of the wound will in all cases be necessary when a shot has to be extracted, as the elasticity of the cornea and sclerotic is such that the opening is always smaller than the body which produces it. In cases where a shot has penetrated the globe and is supposed to be lodged there, the only legitimate [illegible] extraction of some one of its [illegible] I do not think it necessary to let a moment examining with [illegible] such plan is pursued. In a few [illegible] there takes place; the blood effused [illegible] lens is not wounded and the iris [illegible] fully remain in a quiet condition [illegible]

Digitized by Google

become encysted. In these cases, for a time the patient is satisfied with his condition, and is apt to consider that the advice tendered in favour of enucleation was unnecessary and harsh. But the dangerous epoch for such an eye is sure to come sooner or later. The encysting capsule becomes partially absorbed, under some violent exertion or shock to the head or body the shot shifts its position, and severe symptoms immediately set in. I have noticed that the train of events above described is peculiarly liable to occur when the patient is least able to bear it—that is, at a time when some intercurrent disease has reduced his physical powers, especially maladies which have a tendency to produce emaciation. In other cases the original hopeful condition is only maintained for a short time, retrogressive changes set in, and the whole globe undergoes a process of phthisical wasting. In others, again, a subacute inflammatory condition is developed with choroido-iritis or perhaps ossification of the choroid, and the patient is eventually glad to submit to the treatment which the surgeon proposed to him from the first. In by far the majority of cases, however, if nothing is done, violent reaction takes place at once. Acute inflammation is set up with great pain, and considerable constitutional disturbance and a condition of panophthalmitis, or suppurated choroiditis, is established, which in weakly and broken-down subjects may give rise to grave anxiety.

In the event of a patient acquiescing to part with his eye, what operation should we perform? Should we enucleate the whole globe, or should we content ourselves with the ablation of the anterior segment and clearing out the sclerotic cavity, an operation which now goes by the euphemistic term of "exenteration"? To enter upon this question here would be to open up ground which has lately been much controverted. Personally I believe the disadvantages of enucleation have been very much exaggerated, and the advantages of exenteration unduly extolled. Its relative value as a preventive, or rather I should say safeguard, against sympathetic ophthalmia, as compared with enucleation, has yet to be determined. It is more painful, is not less tedious in its performance than enucleation, and is followed at times by an amount of reaction which, in my experience, is very rare in enucleation. I have not been overtaken by the fear of septic poisoning following enucleation, which seems to have invaded continental ophthalmic clinics and threatens some of our own. It must have fallen to my lot within the last sixteen years to have enucleated as many eyes as most persons; yet I have never lost a patient or seen one lost by enucleation. I have seen cases in which slight symptoms of septic poisoning were developed, but these occurred almost invariably when enucleation was performed at the height of acute suppurative inflammation—a practice which I always personally condemn. The danger of this proceeding has, however, long been recognised; and it is in these cases that, perhaps, the operation known as "exenteration" may find a useful sphere for its execution; although I am still doubtful if it has any advantages over a free corneal incision with evacuation of the contents of the globe. All the different operations which have for their object the removal of an eye are as much an "opprobrium" to the ophthalmic surgeon as an amputation is to the general surgeon. They are as distasteful as arithmetic is to the schoolboy, and, if we might be allowed to parody, we might say—

"Exenteration is vexation,
Abscission is as bad,
Neurotomy won't do me,
Though extraction drives me mad."

ST. THOMAS'S HOSPITAL.—On Monday, the 16th inst., the Dean, in the name of the students, past and present, of St. Thomas's, of whom above one hundred were present in the library, presented Mr. Denison, the retiring librarian, with a clock, a purse of 120 guineas, and an illuminated engrossed list of the subscribers to the fund, numbering 309. Dr. Ord briefly touched on the many services of Mr. Denison, the tact which he has shown in advancing school matters, and his happy influence on many generations of students. Mr. Le Gros Clark afterwards, in a short address, emphasised the remarks made by Dr. Ord, and expressed the deep feeling of friendship existing between himself and Mr. Denison. The clock and purse were then presented, and Mr. Denison briefly replied, thanking his friends present for their kindness at all times during his lengthy connexion with the school.

Lectures
ON
INJURIES OF NERVES.

Delivered at the Royal College of Surgeons,

BY ANTHONY A. BOWLBY, F.R.C.S. ENG.,
SURGICAL REGISTRAR AND DEMONSTRATOR OF SURGICAL PATHOLOGY AT ST. BARTHOLOMEW'S HOSPITAL, HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS.

LECTURE II.

(*Concluded from page 971.*)

THE trophic changes in the *joints* and *bones* next claim attention.

With regard to the *joints*, the description by Weir Mitchell must again be given the foremost place, for he was the first to describe the conditions to which I am about to allude.[1] He states that the arthritic lesions may appear either early after the nerve lesion, or else at a later period, when the more immediate symptoms have subsided. Under the latter conditions, "we may then have one articulation—and if only one, a large one—involved; or perhaps all the joints of a finger, or every joint of a hand, or of the entire limb, may suffer. The swelling is never very great, the redness usually slight, and the tenderness on touch or motion exquisite. This condition of things remains, with little change, during weeks or months, and then slowly declines, leaving the joints stiff, enlarged, and somewhat sensitive, especially as to movement. A small proportion of such cases find ready relief, but in many of them the resultant ankylosis proves utterly unconquerable, so that it is vain to try to restore mobility by manipulation or splints." Such is Weir Mitchell's account, and I make no doubt that cases such as he has described have been seen by him. Yet it would be quite a mistake to consider that such are at all common. It has been my fortune to observe for some years past, and to keep constantly under my notice, a large number of cases of nerve injury of most various kinds, yet in none of them have I seen any joint affections so extremely acute and painful as those described by Weir Mitchell. On the other hand, I think that arthritic lesions of a less severe and more chronic kind are amongst the most common results of nerve injury. I have seen them over and over again, and, for my own part, am inclined to consider them as an almost invariable sequel of nerve lesion. It is difficult to understand how they have been missed by many observers; I suppose because they have not been looked for. From my own observations, I should say that within a time varying from one to six weeks after injury to a nerve, the joints will usually be found somewhat stiff. The finger joints have seemed to me to be much more liable to be affected than those of the wrist and elbow, and this not only in cases of injury inflicted low down in the forearm, but also when the wound has been in the upper arm. Usually, but not always, this stiffness has supervened without causing the patient any pain, and, from the fact that the affected parts are often both anæsthetic and partially paralysed, the stiffening of the articulations not infrequently escapes the notice of the patient himself. For several weeks the stiffness increases, and the movements of the joints, both active and passive, gradually diminish. Finally, there appears to be a tolerably firm fibrous ankylosis. The future of the case depends to a great extent on the condition of the injured nerve and on the patient himself, for, if the hand be not used, the stiffness is likely to be much more persistent than if resolute attempts are made to overcome the fixation of the articulations. If the divided nerve resume its functions, the joints are much more likely to again become movable than in cases where no reunion occurs. In many cases they entirely recover, but in others, in spite of all treatment, permanent stiffness results. There is much in the condition of these joints which is suggestive of chronic rheumatism.

It is but rarely that an opportunity is afforded for an examination of the diseased articulations, and I am only aware of one case in which the results of such an examina-

[1] Injuries of Nerves, p. 169.

Digitized by Google

tion have been recorded. The case I allude to is one by Blum,[2] in which the joints of a man whose median nerve had been divided several years previously were examined after death. The cartilages were thinned and softer than natural, and there was some cell proliferation. The articular bone also was rarefied. In 1882 I had the opportunity of examining the hand of a man whose median nerve had been injured about eighteen months previously. An examination of the hand after amputation showed that the nerve had been wounded above the wrist joint, and that a fragment of wood was still buried in its substance. The finger joints were one and all much stiffened. On opening those of the middle finger the capsules were found to be thickened, and the cartilaginous surfaces of the most distal joint united by fibrous tissue. The terminal joint of the ring finger was firmly ankylosed, the union being by bone, and so firm as only to yield to cutting instruments. Microscopically examined, the cartilages were all thinned, and their normal matrix replaced in part by fibrous tissue.

With regard to the *bones*, I have not myself met with a case in which any definite change could be assigned as the result of nerve injury. Instances have, however, been detailed by Blum, Ogle, and Arnozan.[3] In the cases collected by these authors the chief alteration appears to have been a simple atrophy of the osseous tissue, such as might not improbably result from simple disuse. Thus shortening of the femur is mentioned as a result of injury to the sciatic during childhood. In one of Ogle's cases, however, there was not only thinning of the bones of the hand in a case of section of the median nerve, but also bony union between the radius and ulna at their lower ends. Considering therefore the paucity of information on the subject of bone lesions due to nerve injury, I think it may be concluded that they are of comparatively rare occurrence.

Such is a brief account of the various trophic changes that may follow on nerve injury. Instances of them are sufficiently numerous to allow most surgeons to become more or less acquainted with the more common of them, and although I might quote in detail numerous cases in support of the above descriptions, it is needless to enumerate them here. What is of more importance is to inquire into the manner in which section of a nerve trunk so affects the tissues to which it is distributed; and on this point opinions are much at variance. The following are the chief theories:—1. That the changes are due to section of vaso-motor nerves, and consequent irregularity of the blood supply. 2. That they are due to non-use of the paralysed parts. 3. That they are due to irritation of the centrifugal fibres set up by the injury. 4. That they are due to the removal of a special influence exercised by the nerves on the nutrition of the tissues.

The first of these theories has been very extensively supported, but may, I think, be disproved. The arguments adduced in its favour, have been mainly founded upon incorrect views of the vaso-motor system, and conclusions have been incorrectly drawn. It is well known that section of vaso-motor fibres results in the congestion and rise of temperature of the part to which they are supplied, and it has been rather hastily assumed that these changes may readily overstep their bounds and pass on to inflammation and destruction of the affected tissues. These conclusions were drawn on the supposition that the vessels of the part remained permanently in a state of suffusion. Such is not the case. It has been definitely proved by experiments on animals[4] that the vessels of any part are not entirely dependent on their connexion with the medulla oblongata for their nerve supply, but that local vaso-motor centres are present, which are capable of regulating the calibre of the vessels after section of all nerves connecting the latter with the brain and spinal cord. The ear of a rabbit in which the cervical sympathetic has been divided will gradually return to its normal condition, and the former rhythmical contractions of the blood-vessels may again be perceived. The temperature also gradually approximates to that on the opposite side, and subsequently the ear or else the limb of a vertebrate animal, which after section of the main nerve was markedly hotter than its fellow, will gradually become colder by several degrees. It will thus be seen that, while the trophic changes may last a considerable time, the condition which is supposed to give rise to them gradually passes away. Again, while the vessels are turgid and swollen the ear of the rabbit does not atrophy or inflame. On the contrary, the hair grows more luxuriantly (exactly the reverse of that on an extremity whose main nerve is divided) and the nutrition of the whole part is improved. So much, then, for the experimental evidence; but that afforded by pathology is none the less clear in its refutation of the claims made for the influence of the vaso-motor nerves on nutrition. If it can be shown that in certain cases vaso-motor paralysis exists without trophic lesions the independence of these two conditions might be considered demonstrated. Now the first of these conditions is undoubtedly present in a large number of cases of infantile paralysis. It has been shown of late years that the seat of the lesion in these patients lies in the anterior horns of the grey matter of the cord, and most probably in the ganglion cells which are found in this situation. Further, it is well known that many of the vaso-motor nerves leave the spinal medulla by the anterior roots as low down as the eleventh dorsal. These nerves, then, are *a priori* likely to be affected by the lesion in the cord, and it is a matter of clinical observation that the skin over the paralysed muscles is generally congested and its temperature raised, although later on it becomes cold and blue. But infantile paralysis is never accompanied by changes in the nutrition of the skin, always excepting chilblains. There are no subcuticular whitlows, no herpetic eruptions, no loss of hair, and no glossy fingers. Yet, were these lesions dependent on loss of a proper vaso-motor supply, we might fairly expect to find them present in at any rate a certain proportion of these cases, whereas they are conspicuous by their absence. And, on the other hand, we have the testimony of the best authors to prove that trophic changes may be present and the vaso-motor supply still intact. On this point Weir Mitchell[5] writes: "If the vaso-motor nerves were alone responsible for the existence of all the lesions which follow nerve wounds, it would be reasonable to expect always to meet with some rise or fall in temperature. Such, however, is not the case, and I have frequently met with profound trophic changes unattended by thermal perturbations, and the same remark has been made by other neuro-pathologists."

With regard to the second theory, that the wasting and degeneration are due to non-use of the part, it will be well to turn to the case of the muscles, and the claims made for this explanation may be readily set aside. The most distinctive characters of the atrophy following division of a motor nerve are the rapidity of the onset and progress, and the fact that it is accompanied by "degeneration" of the muscle-fibres, so that the affected muscle will not react to faradism, but will do so to galvanism. Now, on the other hand, we have innumerable cases of injury to the spinal cord, of hemiplegia and paraplegia, in which, so long as no destructive disease is in progress in the cord below the seat of the lesion, the paralysed muscles maintain very nearly their normal bulk and do *not* give the *degenerative* reactions to electrical stimuli. Yet these muscles are equally powerless as those whose motor nerve is divided, so that, were the atrophy due to simple non-use, it ought to accompany the one lesion as frequently as it does the other.

Both the third and fourth theories involve the belief in the presence of a direct nervous influence over the process of nutrition, and may be considered together. From an anatomical point of view, the distribution of the terminal nervous filaments to the cells themselves of the different glands, to muscle and connective-tissue fibres, &c., would render it extremely probable that they are intimately concerned both with their functional and vital powers, and a well-known experiment lends proof to this supposition. If the fifth nerve of a rabbit be divided within the skull, the section is followed in about twenty-four hours by a cloudiness of the cornea, and subsequently by a destructive inflammation of the eyeball, frequently by ulceration of the mucous membrane of the lips, gums, and nose. Considering that division of the fifth nerve necessitates an anæsthetic condition of the corresponding side of the face and of the parts involved in the inflammatory process, it seemed at first quite probable that the destructive changes occurring in the eye were the result of an inability to perceive and remove any irritating substances which might be lodged upon it. Snellen accordingly reinvestigated the subject, and expressed his belief that, with due care in protecting the eyeball, the subsequent

[5] Op. cit.

Digitized by Google

inflammation might be avoided. His results have not, however, been obtained by others, and more recent investigations by Merkel have placed the matter in a rather plainer light. This observer states that the fibres, division of which causes the inflammatory conditions above described, are collected together in a small bundle on the inner side of the fifth nerve. If they alone be divided, while the rest of the nerve is intact, sensation of the corresponding side of the face is not lost, but destructive changes occur as before; and, on the other hand, if this bundle be left, but the rest of the nerve be divided, no trophic troubles follow, though anæsthesia of the face ensues. It is therefore assumed that the small tract of fibres alluded to are essentially "trophic."

The numerous experiments bearing on the secretions of saliva by the submaxillary gland also tend to prove the reality of the trophic influence of nerves. When all of those supplied to the above-mentioned gland are divided, and a so-called "paralytic" secretion is set up, the gland tissue ultimately degenerates. This degeneration is not due to cessation of function, for the gland continues to secrete so long as it is able. It may also be proved that secretion (which is but a variety of nutrition) may be started by stimulation of the nerve going to the gland, under the most varied conditions of blood supply, or even in the entire absence of any such fluid. It therefore appears that, in the presence of a copious blood supply and of a continuance of the functional activity, division of the nerves will yet cause an atrophy of the gland structure; while, on the other hand, the presence of the nerves alone is sufficient for the temporary maintenance of the salivary secretion, or, in other words, of the nutrition of the salivary gland.

The argument that the lesions of the skin are due to physical causes, such as pressure, heat, &c., applied to an anæsthetic part, cannot be maintained in its entirety. I have already stated that in some of the cases which have come under my own notice, some external injury has been the starting point of an ulcer or inflammation of the finger; but this is not the case in all, and does not, indeed, apply to many of the trophic changes, such as loss of hair, herpetic eruptions, and others that might be mentioned. Again, in these cases lesions occur while the patient is under observation, and frequently while the extremity is bound up in bandages, &c., which obviate all external influences. Lastly, ulcers, whitlows, &c., are more particularly prone to make their appearance very early after the date of the nerve injury, whilst the anæsthetic condition of the skin, to which they are supposed by some to be due, is much more permanent, and indeed exists under conditions such as manual labour, &c., which might fairly be expected to predispose to inflammatory conditions in a part insensible to pain. Yet, as the anæsthetic condition outlasts the tendency to trophic change, the latter can scarcely be said to be dependent on the former. Many of these arguments have already been used by Dr. Poore in THE LANCET of May 19th, 1877, and to his paper I am much indebted for many suggestions.

Against the theory of the trophic influence of nerves, it has been argued that some tissues—e.g., cartilage and fat—whose nerve supply is either very scanty or entirely absent, get along very well under such conditions, and that therefore nutrition is independent of neurotic influence. Such is by no means necessarily the case, and, indeed, the changes which occur in the above-mentioned tissues after nerve section argue the contrary. Further, it is no argument to say that because any tissue maintains its nutrition, although unconnected with the nervous centres, therefore those which are supplied by nerves can afford to do without. It is only fair to suppose that the more highly developed a structure the more dependent it is on the accurate working of every component part.

All other theories failing, we are therefore driven back to the conclusion that the nerves exercise a direct trophic influence over the tissues. Where, then, is this influence generated, and what are the conditions essential for its integrity? These questions may be briefly answered by stating that so long as any tissue is connected to a healthy nerve centre by healthy nerve fibres its normal nutrition is preserved. Each tissue, then, has its own centre of nutrition in the ganglion cells from which its nerve fibre springs, the tissue, the fibre, and the cell being considered—as Dr. Poore puts it—to be one nutritive unit. One question which offers itself for solution is whether the ganglion on the posterior root acts as a centre for nutritive functions; but the answer must be that, though it may do so, yet *all* the trophic impulses are certainly not generated in it, as is proved by the fact that many of them follow lesions of the cells in the cord itself.

But it may be considered necessary to still further localise the situation of the trophic cells of each fibre, and it only remains to be shown that the latter are not situated higher up the cord than the point at which each of the nerves takes its origin. Simple section of the spinal cord, however, above the point of junction of any particular nerve root, does not in any way interfere with the nutrition of the parts to which the same is distributed; whilst, on the other hand, any lesion involving the nerve cells, from which the fibres take their origin, results in trophic changes in the peripheral tissues. Thus it has been shown by Charcot, in his "Leçons sur les Maladies du Système Nerveux," that in hemiparaplegia there results, on the same side as the lesion, atrophy and degeneration of muscle with disease of the joints, and on the opposite side anæsthesia with acute bedsore, and MM. Déjérine and Leloir, in the *Archives de Physiologie* for 1881, have demonstrated that in cases of acute decubitus the nerves themselves had undergone a degeneration, thus placing the tissues to which they were distributed in a condition similar to that which results from nerve section. Again, in infantile paralysis, a disease in which the cells of the anterior cornu undergo destructive changes, atrophy of the muscles is the most marked symptom, and there can be no doubt that the nerve fibres also degenerate, for transverse sections of them show an increase in the connective tissue and a corresponding diminution of nerve fibres. This condition is evidently the result of a degeneration of the motor nerves, their atrophied remains being seen amongst the normal sensory fibres.

But, granting that the nerves exercise a special control over nutrition, the nerve injury may be supposed to affect the latter in one of two ways: first, by irritation of the trophic fibres; and, secondly, by cutting off the permanent trophic influence which is constantly supplied. Professor Charcot is at present the most notable supporter of the first view; others who formerly held to it, foremost of whom is Dr. Weir Mitchell, having given their adhesion to the latter explanation. In this particular Charcot follows the teaching of Samuel, who thus states his opinion: "The sudden increase in the action of the trophic nerves beyond their ordinary physiological action occasions a rapid development of all nutritive processes throughout the parts to which they are distributed. Acute irritation of these nerves gives birth to a series of abnormal products simply because it stimulates to the highest degree the nutritive processes. The tissues suddenly tumify, the cells increase rapidly, they divide and multiply, and hence the formation of new structures, which no longer resemble the parent one. We are accustomed to name this *tout ensemble* of phenomena inflammation." Under this belief Charcot states his opinion that muscular atrophy occurs most frequently "after contusions, punctures, and incomplete sections of the nerves—that is to say, after traumatic causes which are most liable to produce neuritis, or at any rate neuralgia"; and this is also his opinion as regards other trophic lesions following nerve injury. But this theory is in no way borne out by facts, and I have no hesitation in saying that in by far the larger number of nerve injuries which I have examined, and which have shown trophic lesions more or less marked, the section has been complete, and there has been no reason whatever to suspect any neuritis or neuralgia. Moreover, in most of the cases described by other writers similar conditions have existed. This explanation of Samuel, then, is theoretical; but even on a theoretical ground it falls through; for, as Vulpian has pointed out, the nerve fibres below the seat of section or other injury rapidly degenerate. How, then, can they convey the necessary irritative impulses? I think, therefore, that it may safely be assumed that nerves do exist which exert a direct trophic influence upon the tissues, and that the currents which convey the same are constantly passing. The only question that remains to be considered is whether the existence of special nerve fibres is necessary for the conveyance of trophic impulses, or whether the ordinary sensory and motor tracts suffice. It has been shown that there is nothing incongruous in the idea that any given nerve fibre can convey currents either centripetally or centrifugally, so that there is no *primâ facie* reason why the nerves of motion and sensation should not be amply sufficient for the purpose. And, considering that

Digitized by Google

trophic disturbances very rarely, if ever, occur without some interference with the sensory and motor functions, there is strong probability that the same fibres are capable of conveying the different impulses which are generated in the centres. This point, however, requires further investigation.

STRETCHING THE SPHINCTER IN APOPLEXY.[1]

BY JOHN W. TEALE, M.A.OXON., F.R.C.S.

ON June 8th, 1886, I was summoned by a gentleman to see his wife, whom he had brought from the Midland Counties to place under my care. The lady, aged sixty-four, looked very ill, and was in a highly nervous state. She had a waxy, yellow complexion, and looked wan, anxious, and careworn. She said she had suffered much from constipation, had had severe attacks of what she called "angina pectoris," and that she lived in perpetual dread of having accumulations in the bowels, from which she had suffered. She was clearly possessed of considerable intellectual powers, and when she could forget her physical troubles she was bright and animated. My routine treatment of mild alteratives, stomachics, and aperients proved a complete failure. Mild remedies were ineffectual; more severe ones produced vomiting. So after a few days of fruitless efforts to relieve the bowels, I examined per anum, and found, as I rather anticipated, a very tight sphincter. With considerable difficulty I passed a finger through it into the rectum, which I found distended and loaded with hardened fæces—the cause, no doubt, of the straining, discomfort, and sense of weight. In her feeble health, with shattered nerves, an irritable heart, and albuminous urine, an operation seemed inadmissible. Failing this, I could see no course open except by careful and repeated castor oil enemata, &c., to gradually unload the lower bowel and break down the accumulated mass. For some days this was persisted in, with more or less success. Several times a considerable quantity of old fæces was removed, and often the patient had some gleams of returning health and spirits. July 7th, however, proved a very trying day. No relief could be obtained. In the evening Mrs. E——, with her maid's assistance, gave herself two injections, which were ineffectual, in spite of considerable straining. About 10 P.M. she became very restless and excited, and almost beside herself, wandering from room to room, scarcely recognising those about her, constantly making attempts to relieve the bowels. About 6 A.M. on July 8th, whilst on the night-stool, her maid noticed her face twitching, and, on getting her into bed, she said that these twitchings increased until they amounted to violent convulsions, which continued at intervals. I was sent for, and saw her with my friend, Mr. Beverley, at 6.50 A.M. We found her with slight but well-marked symptoms of paralysis of the left side of the face, which gradually became more decided in character, extending to the left arm and leg. The pupils were regular, somewhat contracted, slightly sensitive to light. There was no stertor, but insensibility was complete. Every few minutes there was a convulsive attack, commencing with twitchings of the left side of the face, extending gradually to the left arm and leg, and then becoming general over both sides of the body, and gradually relaxing without pursuing any definite order. A copious enema of soap and water and olive oil was given, which was retained. At 10 A.M. the enema was still retained, the convulsive attacks continued every few minutes, were more frequent and violent, and insensibility complete. On examining per anum, hardened fæces could be felt floating about in the enema fluid, though, even in her insensible condition, so tight was the sphincter that the finger could only be passed through it with difficulty, nor would it allow a drop of fluid to escape.

Happy thought—why not operate now? In this insensible condition no ether would be required. Nothing could be worse or more hopeless than the present state of things; any change must be for the better. So I stretched the sphincter freely. Immediately the enema fluid poured out, followed by a copious mass of offensive fæces of various stages of antiquity. The convulsions continued as before. At 11 A.M. some beef-tea and forty grains of bromide were injected and retained. At 1 P.M. this injection was repeated. The urine was drawn off by catheter, and on boiling was almost solid albumen; and ice was applied to the head. The convulsive attacks continued pretty regularly until 1.30, when they ceased after the second dose of bromide, and there were slight natural movements of the right side, but none of the left. Temperature 103°; pulse 120, small and weak. In the evening there was another extensive action of the bowels; patient still unconscious.

July 9th.—Fair night; no return of convulsions; bowels again acted freely. Pulse 110; temperature 99·3°. Has slightly moved her left leg. Suppositories given at intervals.

9th.—10.30 A.M.: Patient can swallow sips of water; seems to recognise her husband. Iced water given to moisten the lips.

10th.—When Mr. Beverley saw her at 5.30 A.M. she had passed a restless night; pulse very poor and scarcely countable, about 200; respiration 40. She looked very like sinking, but revived with some essence of beef, with a few drops of brandy added, which she could now swallow.—9 A.M.: Pulse rallied, more regular, 110.—11.30: Suppositories continued. Essence of beef and iced milk and soda given. Gradual return of consciousness after fifty-four hours. Looks eagerly for fluid.

The urine had to be drawn off by catheter for the next three or four days, but the amount of albumen soon became merely nominal.

Mrs. E—— slowly recovered. For some days she misplaced names and words. The right side of the body soon regained power, the left more slowly, and still remains markedly weaker than the right. In about three weeks she returned home. She has again recently visited Scarborough for two or three weeks. The bowels now act easily and naturally without purgatives. She suffers much at times from mental depression, but is clear and animated, and can walk a mile with her husband, sit in a boat with him whilst he catches codlings, and lives out in a Bath chair the most part of the day.

P.S.—I hear that Mrs. E—— died at her home about a month ago. During the early winter she was able to get out in a Bath chair, and, except for fits of extreme despondency, was fairly well, and had little discomfort from the bowels. I think the operation lengthened her life for nearly a year, and also relieved her from suffering. The fact that prolonged constipation from any cause is an important factor in causing apoplexy, when the arterial coats are degenerated, has long been recognised—an argument, no doubt, for the early and effectual surgical relief of affections of the rectum, where they are found to exist.

Scarborough.

COCAINE DOSAGE AND COCAINE ADDICTION.[1]

BY J. B. MATTISON, M.D.

THE recent sad story of the Russian surgeon's suicide from sorrow or remorse due to his belief that a patient had died from an overdose of cocaine points a moral, the import of which demands more than a passing notice. No advent in the therapeutic arena during the last decade has been attended with such varied and extensive claims for favour as cocaine. Its marvellous effect in ophthalmic surgery roused a spirit of experimental research in other directions which has added largely to its well-proved power for good; but, as has been well observed, a potency for good implies a potency for harm, and the risk impends of its ardent advocates being carried by over-enthusiasm beyond the limit of a safe regard for the welfare of their patients or themselves, that may imperil an otherwise well-founded success. Surely it is high time to draw the line to revoice a warning as to the use and abuse of this valued but at the same time toxic drug, lest the roll of alarming, dangerous, and fatal effects from its ignorant or meretricious use be sadly extended, and a reaction engendered, by creating distrust within and without the profession, will damage its good repute, and hinder its use in cases where it would be almost certain of serving us well.

[1] Read before the King's County Medical Society, Feb. 15th [illegible]

the need of this seems all the more called for in view of opinions expressed during the past year, in certain quarters, affirming the harmless character of cocaine—opinions which, I am convinced, are at variance with well-accredited facts, and should not be allowed to pass uncontradicted.

Cocaine seems to have secured for itself a more than usual share of attention apart from the professional press. One metropolitan daily, in particular, has again and again given its columns to a discussion of the topic, and in a somewhat lengthy article not long ago an "eminent but unnamed specialist"—Dr. Francke H. Bosworth—was reported as saying, "There is not a well-authenticated case on record as yet where cocaine has effected injury." In view of cases cited in this paper, and others elsewhere recorded, such a statement is no longer tenable, and any conclusion based thereon as to the harmless nature of cocaine is misleading and incorrect. And the evidence herewith presented weighs even more heavily against an assertion by Dr. Wm. A. Hammond, at a recent meeting of the New York Neurological Society, in the course of his "Remarks on Cocaine and the so-called Cocaine Habit," when, after narrating his taking of eighteen grains as a subcutaneous dose, he asserted "he did not believe any dose that could be taken was dangerous." What might be the outcome of such an opinion put in practice? The Russian surgeon's error of judgment, fatal to his patient and himself, was largely due to his reliance on the asserted use by other surgeons of large doses without ill effect. Might not a like result follow an incautious dependence on Dr. Hammond's disbelief in the toxic power of cocaine? The *Medical Record* (New York) well said of Professor Kolomnin's case, "The experience, though so sad, may not be without its lesson," and put a very pertinent query as to whether "there are not other surgeons who could report very serious if not fatal results from injudiciously or ignorantly using too large a dose of cocaine." Fifty cases herewith noted attest a power in this drug on some patients that warrants caution with all.

Germane to the subject of acute cocaine toxæmia is that of cocaine addiction—these notes are preliminary to a more extensive paper on cocaine inebriety,—the existence of which Dr. Hammond denies. He took half a dozen doses, at intervals of from one to four days, and says "he acquired no habit." But to argue from that that there is no danger of addiction is absurd. Such evidence is worthless. Dr. Hammond might do the same thing with morphia; more, he might take morphia subcutaneously daily for a month or two without creating a "habit"—albeit its ensnaring power is well admitted,—and yet that would not prove its freedom from danger. Not at all; it would merely show his exceptional strength to resist. Many, under a like pressure, would surely succumb. Supporting this opinion, I quote from the last report of Dr. Orpheus Everts (Cincinnati Sanitarium), a gentleman well known in alienistic circles, which report was kindly sent me after my paper was written, who says: "A distinguished physician of New York has recently reported personal experiences tending to discredit the claim that a cocaine habit corresponding to the morphine habit is acquirable. The judgment of this distinguished physician is based upon the evidence of personal experience reported by himself, he having failed to acquire the habit, or any especial fondness for the specific effects of the drug experienced by the hypodermic injection of one, two, three, and finally eighteen grains of the salt, on five or six different occasions in the evening before going to bed. But for the great reputation of this physician as an author and observer of facts, this denial would have but little weight. The testimony is both bad and insufficient. Bad, because reported by himself: the testimony of an intoxicated person respecting his experiences while intoxicated being proverbially untrustworthy; and insufficient, because the experiment was not continued long enough. Many instances might be cited of total failure to establish the morphine habit or habitual drunkenness by the use of six or seven doses of morphine, or six or seven drinks of whisky, one a day, for six or seven days in succession. It is often the case that such experiences end with disgust for the drugs used, instead of a desire to continue their use. There is also much and accumulating testimony by competent observers to the fact of such a habit as is alleged respecting cocaine, which a single opinion will not invalidate, however worthy of consideration."

Cocainism is not the outcome of using the drug at long intervals. Its transient effect and the demand of an impaired nerve status compel frequent taking—more than alcohol or opium,—so that *habitués* have been known to take it ten, twenty, or more times daily; and it is this—growing by what it feeds on—that tends to create and continue the disease. In the early days of chloral one point claimed in its favour was a freedom from risk of "habit," a claim long ago exploded, as cases of chloralism well prove; and yet I venture to assert that there are more cases of cocaine taking in this country to-day—less than three years since its arrival—than of chloral after a period more than six times as long. Dr. Hammond says there may be instances of cocainism as rare as chronic tea taking, and of cases with or after habitual alcohol or opium using; but, as for giving up the use of the drug, he believes every cocaine taker could if he chose. The same opinion regarding opium obtains among some medical men, and the only effective argument against such a fallacy is to place those who hold it under power of that drug, and then have them prove their precept by their practice. While admitting that most instances of cocaine taking are, for obvious reasons, in those who have been or are alcohol or opium *habitués*, especially the latter, I maintain there are cases of pure, primary addiction, and that the number is increasing at home and abroad. Foreign writers have noted them, and they will figure in our records. Notes of one such are here given; others are at command. My experience with a number of cocaine cases makes to me two things certain—there is a pernicious power *per se* in this drug, and it finds in the opium *habitué* a peculiar condition that specially favours its ill effects, making it, for such patients, as has well been said, the "devil's own device" to still further enslave. And this opinion is that of others, for it is the testimony, without exception, so far as I know, of those who have had to do with this disease, that as an intoxicant cocaine is more dangerous than alcohol or opium, and that inebriety resulting from its use is more marked and unyielding than any other form. Dr. Shrady, in the *Medical Record* of Nov. 28th, 1885, says: "To some persons nothing is more fascinating than indulgence in cocaine. It relieves the sense of exhaustion, dispels mental depression, and produces a delicious sense of exhilaration and well-being. The after-effects are at first slight, almost imperceptible, but continual indulgence finally creates a craving which must be satisfied; the individual then becomes nervous, tremulous, sleepless, without appetite, and he is at last reduced to a condition of pitiable neurasthenia." Dr. A. B. Shaw, Physician to St. Vincent Asylum for the Insane, St. Louis, asserts: "Once a man flies to cocaine for relief from 'cares that annoy,' he generally continues with such rapid strides towards such complete subjugation to its bewitching thraldom as but few will ever be rescued from by any power of will which they may be able to bring to their aid." Dr. Everts writes: "It is not only not an antidote to opium poisoning—or, more properly speaking, the organic demand for such drug effects as have been acquired by use,—but is itself a fascinating and dangerous intoxicant, the effects of which may be more difficult to counteract and renounce than are those of opium or its derivatives." Dr. Hughes declares it "a remedy to be used with extreme caution and prudence internally, and the large doses reported as having been given are not ordinarily safe. It will bear watching. It crazes and kills quicker than opium. The possibilities for immediate harm are only not great, but the likelihood of remote damage when tolerance is established is not small. The cocaine habit, more pernicious than the morphine neurosis, is the certain entailment of its frequent administration, and its thraldom is far more tyrannical than the slavery of opium." Erlenmeyer calls cocaine the third scourge of humanity, alcohol and opium being the first and second; and Erlenmeyer is right as to toxic neuroses. He says: "Its characteristic effects are vaso-motor paralysis, accelerated pulse, profuse sweats, dyspnœa and syncope, failure of general nutrition, eyes sunken, skin cadaveric, with mental trouble that sometimes needs restraint"; and I am positive, from cases under my care, that he is correct. I think it for many, notably the large and enlarging number of opium and alcohol *habitués*, the most fascinating, seductive, dangerous, and destructive drug extant; and while admitting its great value in various disordered conditions, earnestly warn all against its careless administration in these cases, and especially insist on the great danger of self-injecting, a course almost certain to entail added ill. To the man who has gone down under opium, and who thinks of taking to cocaine in the hope of being lifted out of the mire, I would say, "Don't," lest he sink the deeper. I have yet to learn of a single instance in which such an effort reached success,

Digitized by Google

but know of many cases where failure followed, or worse—cocaine or coca morphia addiction. And the need of caution against free and frequent use obtains in other cases, for there may come a demand for continued taking that will not be denied.

To summarise. Cocaine may be toxic, sometimes deadly, in large doses. It may give rise to dangerous, or even fatal, symptoms in doses usually deemed safe. The danger, near and remote, is greatest when given under the skin. It may produce a diseased condition, in which the will is prostrate and the patient powerless—a true toxic neurosis, more marked and less hopeful than that from alcohol or opium. Such being my belief, I regard Dr. Hammond's statements mistaken and his conclusions rash and dangerous.

Brooklyn, New York.

MANIPULATION WITHOUT INCISION AS A POSSIBLE TREATMENT IN CERTAIN CASES OF STONE IN THE KIDNEY.

BY WILLIAM H. BENNETT, F.R.C.S.

IN connexion with the recent discussion on Renal Surgery at the Clinical Society, the following case—which, had time allowed, I intended to have mentioned—presents, I venture to think, some points of interest.

An unmarried woman, thirty years old, of a spare habit and nervous disposition, came under my care as an out-patient at St. George's Hospital in September last, complaining of symptoms which led me to suspect that she was the subject of a calculus in the left kidney. At the same time she presented several indications of "hysteria," and stated that she occasionally suffered from fainting attacks, which were quite unconnected with the symptoms on account of which she applied for treatment. Upon examining the abdomen, which was very thin, deep pressure over the left kidney caused considerable sharp pain and threw the superjacent muscles into rigid contraction. The kidney could be distinctly felt and moved with the hand, and seemed of the natural size and form. Taking into consideration the hysterical tendency of the patient, I was unable to decide, in the absence of any very marked abnormality in the urine, with the exception of a very slight deposit of mucus and pus, whether the case was really one of renal calculus or not. Seeing, however, the ease with which the kidney could be felt, partly by reason of the thinness of the patient, I determined, as drugs afforded no relief, to ensure complete relaxation of the abdominal parietes by the administration of an anæsthetic, and then manipulate the kidney as freely as possible, without previously exposing it by incision, with a view, if the case were one of calculus, to disturbing the stone, and, if it were not too large, perhaps bringing about its passage down the ureter, or, in the event of the symptoms being "hysterical," with the hope of producing a mental effect upon the patient sufficient to relieve her distress. She, however, declined the anæsthetic, and I was compelled to attempt the manipulation without its aid. The patient having been laid on her back upon a couch, the fingers of my left hand were dipped deeply into the abdominal wall over the kidney, the right hand being pressed forwards into the loin. By a little management, the muscles being quite flaccid from the patient having become faint, the kidney could be felt quite easily between the two hands, and was kneaded as thoroughly as the circumstances allowed. The patient, although much discontented with the aching and tenderness which the operation seemed to have caused, was well enough to walk away almost directly afterwards.

Two days later she reappeared at the hospital in a more grateful mood, saying that, having suffered much discomfort for the rest of the day after the manipulation, she was seized as she was going to bed with a most acute pain in the affected loin and side of the abdomen. The pain lasted for about half an hour, during which she vomited twice. All at once an uncontrollable desire to micturate occurred, and the pain immediately ceased. No further pain followed, and there can be little doubt that a small calculus had made its way down the ureter into the bladder, although no evidence of its having passed "per urethram" was forthcoming. Moreover, it is quite possible that the manipulation had moved the stone from its resting place in the kidney, and thus brought about its expulsion.

I am aware that an isolated case like the above cannot be taken to necessarily prove much, since the passage of the calculus may have been a mere coincidence; at the same time I am strongly disposed to attribute the result to the manipulation. This view receives some corroboration from a case which was under the care of one of my colleagues, in which the kidney was exposed and examined without the detection of a stone, although shortly afterwards an attack of renal colic was followed by the expulsion of a very small calculus, which had probably been disturbed during the exploration. Other similar cases have, I believe, occurred. As bearing on the same point, I may here say that it seems most probable that when relief has followed the exposure and manipulation of the kidney without the detection of a stone, the result has been due to an alteration in the position of the calculus produced by the kneading to which the organ has been subjected. That calculi of *considerable size* may be overlooked both in the lumbar and combined abdominal and lumbar operation for exposing the kidney when the organ is examined by the fingers only is certain, and it is, I believe, from our experience at St. George's Hospital, equally certain that only stones of the smallest size can escape detection when the kidney is thoroughly explored by acupuncture an operation which has been at present associated with risks which are hardly more than problematic, and at all events less serious than the danger which exists of overlooking calculi of no small size when digital examination is alone employed. Manipulation of the kidney through the parietes without previous incision is possible in certain cases, the number of which is far larger than is generally supposed, when the abdominal walls are not too much loaded with fat, and the muscles have been completely relaxed by the administration of an anæsthetic. Indeed, I believe the kidney to be, as a rule, far more movable and less fixed in the loin in the living subject than it is usually described to be. In conclusion, I venture to suggest that manipulation without incision is a proceeding worthy of trial as a treatment which may possibly prove of utility in certain cases of renal calculus, not too far advanced, as a means of changing the position of the stone and perhaps effecting its expulsion—a possibility, to my mind, sufficiently strong to commend the process to the attention of physicians as an adjunct to the medical treatment of renal calculus.

Chesterfield-street, Mayfair, W.

WILL THE KNEE JERK DIVIDE TYPHOID FEVER FROM MENINGITIS?

BY ANGEL MONEY, M.D., M.R.C.P.,
ASSISTANT PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN AND TO THE VICTORIA PARK CHEST HOSPITAL.

DR. HUGHLINGS JACKSON asserted a month ago at the Medical Society of London that loss of the knee jerk might prove of service in the diagnosis of meningitis from typhoid fever, for he had never known the knee jerk to be absent in typhoid fever, whilst he had found it to be wanting in cases which the necropsy ultimately proved to be meningitis. Our "friend in need," the knee jerk, indeed, appears to be considering its apparent triviality of as much, if not more, value than almost any other clinical phenomenon.

At the same meeting of the Medical Society at which Dr. Jackson's announcement was made, Sir Dyce Duckworth seemed to put a damper on the President's suggestion by asserting that the knee jerk might be absent in undoubted typhoid fever. Two years ago I recorded in THE LANCET my experience of the reflex actions and other nervous phenomena in typhoid fever, phthisis, and other continued fevers (pp. 843 and 1069, vol. ii., 1885), and I can only add that further experience does but confirm what I then stated to be the condition of the reflexes and muscle in these various diseases. The suggestion forces itself upon us that prolonged pyrexia with all that it involves, whether in the way of direct deterioration of protoplasm by the fever heat, or of indirect deterioration of the same by collateral consequences of the pyrexia, is the cause of the very general exaggeration of the deep reflexes and muscular irritability to be found in the diseases mentioned.

Digitized by Google

have not seen a case of typhoid fever in which the knee jerk was lost; though the jerk may have been absent on the day or so preceding death in fatal cases, which are rare at the age at which tubercular meningitis is common. On the other hand, tubercular meningitis does not always cause the disappearance of the knee jerk. Sometimes the knee jerk is increased in cases of undoubted tubercular meningitis, but only, I believe, when the child is unconscious or nearly so. I have even observed, in company with Dr. Gee, that tapping of the patella tendon on one side caused powerful contraction not only of the quadriceps extensor of the same side, but also of the adductors of the thigh of the opposite side, in a case of tubercular meningitis. Such phenomena will not be found to be very uncommon if they be diligently searched for. I have myself seen them in diphtheritic paralysis, as well as in tubercular meningitis and phthisis. In order to answer so far as is possible the question which forms the title of this brief communication I shall formulate the following propositions: Given a case of fever with morbid mental phenomena, without a typical rash, optic neuritis, or choroidal tubercle, or any sign of cranial nerve paralysis or irritation, if the knee jerk is lost on both sides during the illness, and the wasting of muscle is unattended with loss of response to the faradaic current, the diagnosis should be meningitis rather than typhoid fever. If the knee jerk be exaggerated, and if there be ankle clonus, no certain conclusion can be drawn, for these conditions occur both in typhoid fever and in meningitis (and other conditions). But I am inclined to assert—though on this point I desire further observation and investigation—that increase of the jerks (with or without ankle clonus), accompanied by lively spontaneous flickerings (fibrillar contractions) of the muscles, is much more likely to be due to prolonged pyrexia than to direct disturbance of the nervous functions from meningitis or other nervous irritation. If typhoid fever be complicated with myelitis or meningitis—complications of rare occurrence—then the jerk may be lost, but with a fairly large experience (I have carefully tested the point in twenty-five cases) I have never known it to be absent; whilst in tubercular meningitis its disappearance for a few hours, or a day, or a few days, is by no means rare. A variable state of the knee jerk—e.g., one day present, next day absent, and a third increased—points to meningitis, not fever.

To make what may be considered a curious comparison, I should think that the differential diagnosis of meningitis from mere fevers might be assisted far more by the state of the knee jerk than by the swelling of the spleen; for unless the splenic enlargement be enormous, tubercle as well as typhoid fever and other diseases—e.g., pyæmia—will account for the splenic swelling; whereas absence of the knee jerk, or rather ascertained disappearance of the same, is practically never met with as the simple outcome of prolonged pyrexia.

Harley-street, W.

A CASE OF HYDROPHOBIA IN A CHILD.

BY R. A. JAMIESON, M.A.,

CONSULTING SURGEON TO THE IMPERIAL MARITIME CUSTOMS IN CHINA.

L——, an English child, male, aged three years and a half, was knocked down by a stray dog on January 4th, 1886, and severely torn about the face by the animal's teeth and claws. The mouth was laid open through the lower lip by a perpendicular cut beginning at the left angle and extending an inch and a half downwards; and through the upper lip by an almost horizontal cut, about one inch in length, reaching from the right nostril towards the left side. The skin and areolar tissue of the right lower eyelid were torn from the muscle, leaving a narrow border of skin perhaps one-sixth of an inch wide below the ciliary margin. The portion thus torn formed nearly a semicircle of one inch radius, the centre corresponding to the middle point of the edge of the lower lid. It was split more or less horizontally by a laceration extending from the internal canthus about half way across the flap, and was rolled into a ball at the inner angle of the orbit, being retained by two slender points of attachment separated by the horizontal laceration, and corresponding to the anterior edge of the lacrymal bone. When unfolded, the flap was bruised and cold, and its external extremity severely crushed. Under chloroform it was replaced, and the edges sutured and smeared with iodoform ointment. The other wounds were united and covered with collodion. On Jan. 23rd all the wounds had healed, but in consequence of sloughing of the external edge of the flap some slight eversion of the lower lid was threatened. Bleeding had been profuse from all the wounds at the time of the accident. Taking this and the condition and position of the injury to the lower lid into consideration, I did not cauterise the exposed surfaces. It was subsequently remembered that on the 26th and 27th (twenty-third and twenty-fourth days) the child made excuses not to drink milk or tea. He ate, however, porridge and milk, bread and soup, &c. On the 28th he ate a quantity of fruit, and seemed to suffer from indigestion. Some castor oil was administered with great difficulty, and he had a warm bath. When he was on the point of being put into the bath he sprang from his mother's arms in apparent fright, and climbed up the back of a high chair "like a monkey." He soon, however, came down, got into the tub himself, and wished to stay in the water. Next morning (29th), when coaxed to take some milk, he would only answer, "by and by," and when at last persuaded to make the attempt he pushed the cup from him. There was no spasm, no mucus in the fauces, and no aerophobia. During the day he repeatedly asked for milk &c., but refused everything as soon as it was brought, and was very restless and peevish. A mustard bath was administered at some friend's suggestion, and it did not frighten him. At 7 P.M. he was extremely nervous, and his legs were trembling. There was no intolerance of light (in fact he seemed pleased to look at the gas), and he paid no attention to the splashing of water close by him. At 10.30 P.M. he was delirious and saw spectres. The slightest touch on the head now produced spasm of respiration. At 11.15 P.M. the following note was made: "Frequent spasmodic arrest of breathing, immediately followed by forced inspiration in a series of short gasps. He starts up, momentarily stiff in all his limbs, but there is no clonic convulsions. His expression is maniacal, and he agitates his hands battling with spectres. This lasts for about forty-five seconds, when he becomes calm, recognises the people round him, and talks rationally, asking his father, for instance, to 'send the doctor away,' and replying, when a drink was offered him, that he did not want it. Between the grand attacks he has minor seizures, due apparently to spasm of the fauces; he retches violently, but brings nothing up." At 11.30 P.M., and again an hour afterwards, injections of one-tenth of a grain of morphia each time were administered, but with hardly perceptible effect, the pupils remaining dilated rather than contracted. On the 30th, from 1.30 to 5.30 A.M. he spent in spasm of the entire body, so violent as to jerk him out of his mother's arms and fling him two feet from her on to the bed on which she was sitting. At 4 A.M. he began to hawk up viscid mucus, which collected at the corner of his mouth; asking constantly for milk, but refusing it before it could be brought. At 5.30 A.M. one-tenth of a grain of morphia was injected. He did not during this period seem to lose consciousness under the attacks, and in the interval he was perfectly sensible, and his voice was unaltered. He passed urine three times between 1 and 5 A.M. standing up, and was not affected by the sound of falling water. The urine became milky on boiling; it was cleared by a drop of nitric acid. An attempt to relieve thirst by a warm water enema had to be abandoned, as it induced violent general spasm. Thinking it better to keep the room dark, the gas was lowered, but the change in the light brought on a spasm, and he begged that it should remain bright. At 6 A.M., the last dose of morphia showing no effect beyond causing moderate contraction of the pupils, the saliva becoming more and more abundant, the spasms more violent, frequent, and prolonged, and death seeming imminent, I again gave one-tenth of a grain. All the injections were given in the right buttock. There appeared to be complete insensibility of the skin in this region, as the child made no complaint of the needle prick. Immediately before giving this injection the following note was made: "Each spasm begins with a gulp, followed by the appearance of a little froth at the corners of the mouth. He then momentarily ceases to recognise the people round him, sees some terrifying sight, the lips become livid, he opens his mouth widely in prolonged effort to get air, and a quantity of viscid saliva is suddenly secreted which he hawks up. The end of the attack is marked by his speaking about some indifferent thing in a clear, strong, and natural voice. Conjunctivæ injected face pale, lips ashy."

Digitized by Google

The breathing now became deep and regular, and colour returned to the cheeks and lips. He seemed to sleep until 7 A.M., when he roused and asked for some toys. At 7.30 there was an extremely severe seizure, caused apparently by a sudden profuse secretion of mucus in the fauces. This collection, after a tremendous effort, he swallowed. He spoke of some water which he saw in a glass standing on the mantelpiece six or eight feet from him, but was not affected by looking at it. Another attack threatening at 7.35, I again gave one-tenth of a grain of morphia. He remained quiet, talking occasionally, and vomited some brown fluid. At 7.50 he inquired whether I had gone away, and then asked to be held so that he could see the gas. At 8 A.M., without loss of consciousness, there was a clonic convulsion of the left arm and of both hands. Both thumbs were flexed into the palms, but not firmly. Secretion in fauces more and more profuse, but no spitting. Breathing consisted of violent shallow inpirations, rapid expiration, and long pauses. Vomiting of brown fluid continued, which was now darker and contained altered blood. At 8.30 A.M. a grand attack was imminent. Morphia was again given, after which he dozed. No further violent spasms, but constant starting and continual vomiting. Pupils slightly contracted. At 10 A.M. corneæ muddy, and commencing ulceration of lower external quadrant on left side. Profuse muco-purulent discharge from conjunctivæ. Large quantities of grumous fluid vomited. No further secretion of mucus in the fauces occurred. He lay quietly in bed, disturbed from time to time by convulsion of the left side of the body and face until now, when in a violent and general convulsion he died.

I have detailed this case with what may seem tedious minuteness; but while it falls to the lot of but few practitioners to observe any considerable number of cases of hydrophobia, there are scarcely any opportunities for observing the disease in infancy. This fact may be my excuse. It is only in childhood that the course of the malady is uncomplicated by the mental condition arising out of knowledge of the inevitable termination close at hand; and although this condition is often, if not generally, betrayed by but few outward signs, it cannot fail to influence the psychical symptoms manifested.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF HÆMOPHILIA.

BY HERBERT W. PAGE, M.A. CANTAB., F.R.C.S. ENG.,
LECTURER ON SURGERY, ST. MARY'S HOSPITAL.

THE publication by Dr. Skelton of his "Three Cases of Hæmophilia in the same Family" induces me to publish a clinical note of a case recently under my care in St. Mary's Hospital, where the patient was a member of a family in which ten members, males and females, of three successive generations were hæmophilic, and in which there was some departure from the ordinary rule of transmission.

A young man aged twenty-two, tall, anæmic, and thin, was admitted with an extensive swelling of the left thigh reaching from the knee to the groin, and from its physical characteristics evidently due to blood extravasated beneath the muscles. Seven weeks previously he had been laid up with so-called rheumatism in his left knee, which left it stiff; and five days before admission he had stumbled and fallen, and his leg was bent forcibly under him. It seemed to him as if "the flesh was being torn from the bone"; he suffered great pain, and the thigh rapidly swelled. We very early suspected he was a bleeder, and learned from him that he had had profuse hæmorrhage at one time from the extraction of a tooth, that he was subject to epistaxis, had bled furiously some two years ago from the opening of an abscess, and three years before had been laid up for many weeks with a swelling of the right knee, which, he said, was thought at first to be a sarcoma, but which in all probability was an intra-articular hæmorrhage. His high temperature, and the considerable tenderness with some redness at one point of the thigh, led us to suspect suppuration might supervene; and as the necessity for making an incision was above all things to be avoided, the limb was placed at perfect rest on a Macintyre splint, after having been carefully bandaged from toes to groin. He was soon easier, the swelling at once began to diminish, and in seven weeks had entirely gone, some slight stiffness of the knee alone remaining when he was discharged at the end of two months.

His family history was very carefully worked out by my dresser and friend, Mr. Davis; and although it was impossible for him to see the various members of the family, he nevertheless elicited the following facts. Paternal grandparents healthy; maternal grandmother was in early life a bleeder, though in what precise way it was not known. She and her husband were not related to each other, nor were her own parents. She had eleven children, of whom the first, second, fourth, sixth, seventh, and eighth (all males) are dead—a startling mortality; but whether any were bleeders or not it was impossible to discover. As, however, the ninth, a living male, is a bleeder, it seems probable that some of his elder brothers may have been bleeders also. One of these brothers had died in infancy, and none are known to have died of hæmorrhage. The third, fifth, tenth, and eleventh (females) are alive, and all are bleeders. The third child, and eldest daughter, now aged sixty, is the patient's mother, and some of her children alone, of the third generation, are, so far, bleeders. Her family consists of two daughters and three sons. The three eldest are daughters, all bleeders, if a history of severe epistaxis and free bleeding is sufficient to establish this fact. The fourth is the patient; then come a daughter and two sons, of whom none are bleeders. It is true that these three, the youngest brother and sisters of the patient, may perchance not yet have had the opportunity of showing their diathesis, but it may be hoped that their immunity is an indication that the hæmophilia is tending to die out. What may have been the original cause of the hæmophilia in the first generation it is of course impossible to say; but this pedigree affords, at any rate, a good example of a morbid diathesis becoming rapidly developed to an extreme degree in the second generation—so much so that the children were affected certainly from the third down to the very youngest member (the eleventh) of the family; and possibly declining again, and it may be disappearing altogether, in the third generation, the three youngest grandchildren not being affected. Of the fourth generation, there are two, a male and a female, children of the patient's eldest sister, who are not bleeders. A noticeable feature, also, in this history is the fact that males and females seem to have been affected in an equal degree, contrary to the supposed usual rule that the males alone or most chiefly suffer, and that while the males inherit the disease it is through their mothers who themselves remain unaffected.

SOME REMARKS ON A CASE OF SMALL-POX ARISING IN MID-OCEAN.

BY CHARLES J. POWER, M.A. CANTAB., M.D.
LATE SENIOR HOUSE-SURGEON, METROPOLITAN FREE HOSPITAL.

THE following communication may be interesting in connexion with the leading article on "Small-pox in Australasia," which appeared in THE LANCET of January 1st of this year.

In April of last year, two days after leaving Aden, a case of variola arose amongst the passengers of the Orient Company's R.M.S. *Chimborazo*. The patient was an Italian steerage passenger, who embarked at Naples. The diagnosis of variola was certain. I had the patient removed to one of the boats, which was partly covered in and otherwise fitted up for his accommodation. One of the patient's compatriots volunteered to act as nurse, and he was strictly confined to the boat. No one was allowed near the patient but myself, and the part of the deck near the boat was fenced off. The food of both patient and nurse was drawn up by the latter, and all scraps of food, &c., were lowered down at night and at once thrown overboard. In addition to this, the ship was repeatedly fumigated with sulphur, steam, &c. The supply of lymph on board led me to vaccinate all the most urgent cases. As I was the only surgeon on board I had to move about among the passengers in the exercise of my duties; and I wore a special suit of clothes, well sprinkled with

Digitized by Google

tion, for visiting the patient, avoided touching him, and took a bath immediately after my visit. On our arrival at Adelaide those of the passengers who had reached their destination were placed in quarantine, and the boat in which the patient was (who was now becoming convalescent, the scabs commencing to fall off, showing well-marked "pits") lowered into the sea, and taken off to a separate island to undergo his quarantine. We subsequently arrived at Sydney, where we were placed in quarantine for three weeks, the time to date from our arrival at Adelaide. All the rest of our passengers were landed on the quarantine ground at Melbourne and Sydney. The patient, who had never been vaccinated, had confluent small-pox, highest temperature 104°, never had any delirium, and made a good recovery. At the commencement of disease there was an uncertain history of vomiting and pain in the back. The "secondary fever" was well marked. None of the passengers, officers, or crew subsequently contracted variola. I believe the main factor in preventing the spread of the disease was the early isolation of the patient. Variola, never easy to diagnose, is rendered much more difficult in hot climates. I have seen cases of "prickly heat" closely simulating variola, and a mosquito bite which has not been scratched has exactly the hard, shot-like feel of a papule in small-pox. Of course these cases will not have the constitutional disturbance which variola usually has, though I have seen constitutional symptoms in bad cases of prickly heat, and these symptoms in modified variola are sometimes, at any rate at the commencement of the disease, very slight. I can strongly recommend the treatment of patients suffering from variola in a boat which is partly covered in, thus forming a tent, provided the climate is suitable.

The Australians have a great dread of variola, yet vaccination is not compulsory amongst the inhabitants. The sanitary authorities made a great point about the vaccination of our passengers and crew. All who had not been successfully vaccinated within two years had to undergo the operation or remain in quarantine for an indefinite period. Some of the quarantine regulations are very strict, but in other matters the sanitary authorities are lax.

Aldermey-street, S.W.

CASE OF THYROTOMY FOR EPITHELIOMA OF THE LARYNX.

By W. R. H. STEWART,

AURAL SURGEON TO THE GREAT NORTHERN CENTRAL HOSPITAL, SURGEON TO THE LONDON THROAT HOSPITAL, ETC.

B. K——, aged forty-five, a chimney sweep, came under my care in 1883. A slightly-made, delicate-looking man, married, no children; does not remember his parents; one brother and two sisters living, all healthy; no history of hereditary taint; had been a sweep from boyhood; had suffered from difficulty of breathing for the last six months, which was much worse lately; paroxysmal cough; had lost flesh. When first seen there were marked laryngeal stridor, harshness of voice, and severe attacks of dyspnœa. There were no enlarged glands in the neck. Laryngeal examination revealed a rather large, irregular growth, springing from below the right vocal cord, and projecting across the larynx. A portion removed by laryngeal forceps and placed under the microscope proved to be epithelioma. A preliminary tracheotomy was performed, and when the patient was sufficiently recovered, the growth being large, thyrotomy was determined on. Ether having been administered and a tampon tube inserted in place of the ordinary one, the superficial structures were divided in the middle line, the thyroid cartilage was then carefully cut through in its whole length with a knife (there was no ossification), and the alæ drawn aside with retractors. Through this small opening the tumour was seen to be growing from the under surface of the right vocal cord, and involving the soft tissues around. It was seized with forceps and as much as possible of the tumour, with the vocal cord and adjacent structures, cut away with small curved scissors; the remains of the growth were then scraped away with a sharp spoon, and solid nitrate of silver applied. The hæmorrhage was rather profuse at first, but soon stopped. The alæ were then carefully adapted and brought together with silver sutures, strapping applied to the external wound, a drainage tube inserted, and antiseptic dressings used. The tampon tube was left in for twenty-four hours, after which an ordinary tube was used for a couple of days. The patient was entirely fed for the first week by nutrient enemata. There was no sign of perichondritis, and the patient made an uninterrupted recovery. At the end of the fourth week, when he left at his own desire for domestic reasons, the external wound had completely healed and the internal one was cicatrised over, but up to that time he had not regained his voice. The cartilages, however, having firmly united, would lead one soon to expect a complete return. There was no sign of a recurrence of the growth.

I unfortunately lost sight of the case, as I was obliged soon after to leave England on account of my own health, and subsequent inquiries have failed to find the man. Where possible, either the above operation, or removal of half the thyroid, as illustrated in a case recently published in a medical journal, is, I think, preferable to the extremely fatal one of excision of the larynx. I strongly advise preliminary tracheotomy with retention of the tube for some days after the operation, and also feeding per rectum.

Devonshire-street, W.

HERNIOTOMY IN A VERY YOUNG CHILD.

By J. LIONEL STRETTON.

H. G——, born July 28th, 1886; male child. On Aug. 16th a swelling was noticed in the right scrotum; this was found to be a rupture, and was reduced by my assistant. On Aug. 25th the rupture again appeared, and all attempts at reduction failed. Fæcal vomiting set in, and the child was evidently losing ground. There had been no evacuation, and, so far as the mother could tell, no passage of flatus since the rupture appeared, thirty hours previously to my seeing him. Under such circumstances I determined upon immediate operation. Chloroform was administered and an attempt made to reduce the rupture; this failing, I made an incision over the swelling about three-quarters of an inch in length, and exposed the bowel, which was an exceedingly difficult proceeding in such a small space. The stricture, which appeared to be situated at the inner ring, was exceedingly tight, and required two or three nicks before the bowel, which was in a healthy-looking state, could be reduced. Silk sutures were employed and the wound dressed with oiled lint. Ordered half a minim of tincture of opium every four hours; the mother to continue suckling.—Aug. 27th: Passed flatus last night; no sickness since operation. Temperature normal. Takes breast well. Wound looks healthy.—28th: There were two natural evacuations during the night. Child seems quite well. A little local inflammation round the wound.—Sept. 1st: The bowels have acted regularly. Sutures removed. Slight gaping.—7th: The wound has quite healed; the child has gained much in flesh, and appears to be quite well. There is no bulging, even on violent crying.

Remarks.—This case is remarkable on account of the age of the child, the immediate subsidence of all symptoms after operation, and the rapid recovery. I have been unable to find any account of operation in so young a child; but when I take into consideration all the disadvantages I laboured under in this case I should not despair of success in even younger subjects. He was the child of poor parents, and was brought to my house for me to examine him, and knowing that he was in better air and surroundings I operated at once, and he was carried home in a blanket, and certainly did not receive any skilled nursing afterwards, nor was it possible to prevent the dressings being soaked in urine.

Kidderminster.

A RARE COMPLICATION IN A CASE OF PLACENTA PRÆVIA.

By GEORGE D. LOGAN, M.B. & C.M. ED.

IN July last I was called to see a woman who lived four miles away, and who was said to be in labour and bleeding to death. On arrival I found her blanched and in a cold sweat. Her pulse was quick, irregular, and feeble. I was informed by an attendant that the patient, who was a primipara, had fainted twice, and that the pains were neither so strong as they had been, nor so frequent. She

Digitized by Google

had an attack of bleeding about three weeks previously for the first time, but it was not severe, and there had been a recurrence of it on one or two other occasions. It was now excessive. On examining per vaginam the placenta was found presenting and slightly detached on the left side, but the os uteri was not very dilatable. Considering this, together with the facts that the liquor amnii had escaped, and that I could not discover the fœtal heart sounds, I made up my mind to detach and extract the placenta, thinking it would give the best chance of recovery to the mother. After having detached the placenta, I could not, however, extract it, but the bleeding was considerably diminished. I now plugged the vagina with lint and administered ether hypodermically, as the stomach rejected everything immediately after it had been swallowed. On removing the plug about half an hour later, the os uteri was more dilatable. There was still considerable hæmorrhage, so I determined to turn and deliver the child. While passing my hand into the uterus the latter suddenly contracted, and after this had passed off the uterine surface felt warmer than the placental, due no doubt to a renewed flow of blood from the uterine vessels. After turning, the child was easily delivered, but it was dead. It now became evident why the placenta could not be extracted; it was intimately adherent to the head of the child. As nearly as could be calculated, the surface of attachment measured in diameter about two inches and a half, and the situation of its centre was a point a little below the posterior fontanelle. The neck of the child was very short, the head having the appearance of being attached to the trunk, without neck at all. The forehead receded very much, so that the supra-orbital ridges became very prominent, as were also the eyes; the bridge of the nose extended upwards beyond the eyes and separated them. The cord was quite natural both at its origin and insertion, and in every other respect the child, which was a male, was well developed. The mother made a good recovery.

ST. GEORGE'S HOSPITAL.

A COMPLICATED CASE OF INTUSSUSCEPTION IN A CHILD; OPERATION AFTER SEVENTY-TWO HOURS; DEATH; NECROPSY; REMARKS.

(Under the care of Mr. DENT.)

THE treatment of intussusception is a subject which has occupied the attention of practical surgeons for years. Whether to proceed immediately to the performance of abdominal section on the failure of the injection of air or fluids into the bowel, or to try again these methods even though the patient is *in extremis*, has been, and still is in many cases, a doubtful point with practitioners. There is no doubt that an early abdominal operation is more likely to be successful than one performed later, when the patient is exhausted by vomiting and early peritonitis. Still, there are cases in which the employment of injection of air or fluid has succeeded when the intussusception has recurred after reduction, and in which this treatment has ultimately proved successful. The difficulty is to determine when the case is one of incomplete reduction or of complete reduction with recurrence of the original condition of intussusception. We would refer our readers to the remarks on this case.

Annie O——, aged six months, was admitted on Jan. 31st last. On the 28th she was seen by a medical man who was told that the child had had symptoms of obstruction for about twelve hours. An intussusception of considerable size was found, easily felt through the abdominal walls and per rectum. The symptoms were not urgent. On the 29th, nothing having passed but mucus, an attempt was made to reduce the intussusception by means of enemata. On the 30th, under chloroform, the same plan of treatment was again adopted. The tumour appeared to be to a great extent though not entirely reduced, for it still could be felt through the abdominal walls. Next day the tumour came down as low as before, and the child being worse she was sent to the hospital for operation.

On admission there was evidence of rather severe abdominal pain and peritonitis. The vomiting was tolerably constant and the obstruction complete. The tumour could easily be felt through the wall of the rectum, low down in the pelvis, but its extent could not be ascertained. In view of the peritonitis it seemed highly improbable that the intussusception could be reduced, and it was decided to open the abdomen at once under an anæsthetic. An incision two and a half inches in length was made in the middle line below the umbilicus. As was expected, the distended coils of intestine protruded immediately the peritoneum was opened, and throughout the operation gave the greatest difficulty. Search was made in the neighbourhood of the right sacro-iliac joint for the obstruction. A double coil of empty small intestine now came into view, and on being traced out was found to be about fifteen inches in length and to pass down to the left side of the pelvic cavity. Further examination revealed that this loop of gut was tightly constricted by the sharp edge of a fold of mesentery attached to the ileum, this portion of intestine being buried deeply down in the pelvic cavity. The sharp constricting edge was cut and the portion of small intestine forming the internal hernia released, though not without difficulty. The child was now so exhausted that it was necessary to proceed with the utmost rapidity. Attention was next turned to the intussusception, which proved to be ileo-colic as well as ileo-cæcal, and six or eight inches in length. The cæcum lay in the middle line opposite the first vertebra of the sacrum, while the transverse and descending colon were dragged down and stretched across the brim of the pelvis on the left side. The entering gut was pretty firmly adherent to the intussuscipiens, and considerable traction was required to draw out the intussusception. The peritoneal coat was slightly lacerated in two places in releasing the intestine. The apex of the cæcum, together with the vermiform appendix, was also invaginated upwards into the ascending colon, the whole of the appendix being buried; this second invagination was easily drawn down. The invaginated bowel was dark, and patches of it were rough from lymph. By hooking the fingers under the upper angle of the wound and lifting the abdominal wall well up, the protruding intestine was easily reduced and the wound closed as quickly as possible. The child, who was almost moribund after the severe operation, rallied considerably after a while. The pulse returned, the limbs became warm, and she began to cry. About five hours later, however, she died very suddenly.

At the necropsy, the coils of intestine were found to be lightly adherent together. The lumen of the intestine was pervious throughout, but the coil of gut that had formed the internal hernia was still empty and flaccid. The edge of the ileo-cæcal opening was stretched and thickened, and the mucous membrane ulcerated. There was no blood in the peritoneal cavity. The other organs were all healthy.

Remarks by Mr. DENT.—No cause could be assigned for the intussusception, and the child had previously been in good health. In view of the condition of the parts found at the time of operation and at the post-mortem examination, it is hard to believe that the first attempt at reduction really relieved the obstruction at all. The internal hernia, no doubt, was a secondary affection, and resulted from the dragging down of the colon as the intussusception enlarged. Still, from the appearance of the gut, it must have formed early. The noticeable points of the case are—(1) that the intussusception was ileo-colic as well as ileo-cæcal; (2) the complicated nature of the obstruction; and (3) that it was possible to reduce this completely by operation. In acute intussusception such as in this case, in which vomiting occurred early, abdominal section, to my mind, offers the only prospect of relief. After thirty hours the prospect very rapidly diminishes. The case was from the first attended to promptly, and orthodox treatment was skilfully employed. The child was submitted to operation much earlier than is usually the case, yet the chance of success was very slight, seeing that peritonitis had already commenced. In this, as in so many cases of intestinal obstruction, although the operation was performed comparatively early, the epitaph must still be "too late." There is, I think, more tendency to procrastinate in cases of

Digitized by Google

intussusception than in other forms of obstruction, and this record may therefore prove instructive. The hope that the invagination may slough and come away is a very delusive one; for, as Mr. Treves has pointed out, only a small proportion of patients in whom this occurs actually recover. Obviously in this case the obstruction would still have existed, even though the intussusception had sloughed off. The greater the number of cases recorded, the more will knowledge advance; and the more knowledge advances, the more will the principles that guide the treatment of internal and external strangulated hernia tend to assimilate.

CROYDON INFIRMARY.

A CASE OF ACUTE INTERNAL STRANGULATION.

(Under the care of Mr. F. W. CLARK, L.R.C.P., M.R.C.S.).

F. B——a Polish Jew, aged twenty-nine, was admitted into the infirmary on Tuesday, July 6th, 1886, at 5 P.M. He was a fairly well nourished man, a painter by trade, and on admission he complained of great pain in the abdomen and intense thirst. His face had a drawn and anxious expression; there was pallor of the surface; the tongue dry and coated; and he lay in bed on his back with his knees drawn up, and was evidently in great suffering. The abdomen was distended and tympanitic, and was tender all over, but especially so over the hypogastric region. The pulse was small, hard, and rapid—"wiry,"—and the respiration thoracic. The patient dated the onset of his illness from the previous Saturday (four days), on which day he had partaken largely of some tinned salmon, and since that meal he had suffered from pain in the abdomen, which had gradually increased. There was no history of vomiting, but it was elicited that his bowels had not been opened since the onset of the pain in the abdomen. There was no external hernia. The patient asked repeatedly for a catheter; a No. 10 silver English catheter was accordingly passed into the bladder without any difficulty, and four ounces of clear, high-coloured urine were drawn off, containing no traces of blood. Turpentine stupes were at once applied to the abdomen, and he was given a grain of opium by the mouth; and was ordered two drachms of brandy every half-hour, diluted with small quantities of warm water. During the night the patient twice got out of bed to get to the night-stool, and, with much straining, he passed about two ounces of very dark-coloured fluid blood. Vomiting set in at 8 P.M. the patient bringing up at this time the brandy which had been given him, and he continued to vomit intermittently until his death at 1 A.M., eight hours after admission, the vomited matters not becoming stercoraceous until within an hour of his death.

At the necropsy, made thirteen hours after death, a large mass of gangrenous small intestine was found lying in the pelvic cavity, while the rest of the bowel was matted together by recent lymph. The gangrenous bowel was found to have been strangulated by a rounded fibrous cord, about an inch and a half in length, stretching between two adjacent coils of small intestine in such a manner as to form a loop through which the strangulated bowel had passed. This band had evidently been formed by the stretching of an old peritonitic adhesion of the intestine.

Remarks by Mr. CLARK.—Apart from the comparative rarity of such cases of acute internal strangulation, this case, I think, presents several features which are of especial interest. One is so apt to look upon fæcal vomiting as inseparable from strangulation of the bowel, whether external or internal, that the marked absence of this symptom in the present case until the patient was *in extremis*, rendered the cause of the peritonitis at first very obscure. The persistent reference by the patient of all his pain to the bladder, coupled with the marked tenderness over the hypogastric region, suggested a rupture of that viscus as the possible cause of the peritonitis, but the result of the catheterisation completely negatived such a conclusion. Another feature which adds an interest to the case is the nature of the strangulating band. It is well known that fibrous adhesions of adjacent segments of bowel, the result of an old peritonitis, will, under the influence of the peristaltic contraction of the bowel, gradually elongate to form bands of fibrous tissue stretching across the peritoneal cavity, and these bands or cords may, as in the present case, occasionally prove the direct cause of an internal strangulation. It is most probable that, had the patient been seen earlier—for he had been ill for four days before admission, yet had sought no medical advice,—and had the condition been correctly diagnosed, an abdominal section, followed by the division of the strangulating band, might have been the means of saving his life. Other points of interest in the case are: firstly, the fact that the patient was a painter by trade, and so liable to attacks of intestinal colic; and, secondly, the suspicion of irritant poisoning, which was excited by the history that the symptoms dated from the time at which he had partaken largely of some tinned fish.

DORSET COUNTY HOSPITAL.

A CASE OF SUPRAPUBIC LITHOTOMY.

(Under the care of Mr. A. EMSON.)

FOR the following notes we are indebted to Mr. F. J. Malden, house-surgeon.

R. W——, a quarryman, aged sixty, residing at Portland, was admitted on Oct. 14th, 1886, with symptoms of stone in the bladder. The symptoms had not been severe, but had been present over a period of four years. It was only a few days before he came to the hospital that he was obliged to give up his work, on account of frequency of micturition, hæmaturia, and pain after the act of micturition.

At the time of admission the urine was alkaline, specific gravity 1020, no albumen, muco-purulent. The stone was readily detected by means of a No. 8 sound with small curve, and the ring heard distinctly. The stone, which seemed to fit in the concavity of the sound, was situated in the right lower part of the bladder. The attempt to pass the grooved "staff" on two previous occasions having failed on account of the enlargement of the prostate, it was determined to remove the stone by the suprapubic instead of the lateral method. The operation was performed on Jan. 11th, 1887. The rectal bag was first inserted, and twelve ounces of warm water introduced with a syringe; the bladder was then distended by means of eight ounces of carbolic lotion (1 in 1000), and the penis tied with a soft rubber catheter. An incision was now made about three inches long in the middle line, coming well down on to the front of the pubes; after this the tissues were separated by means of a director, handle of scalpel, and finger nail until the wall of the bladder came in view. There was no hæmorrhage to speak of, no vessel needing ligature. The hook used in this case for elevating the walls of the bladder was one found particularly serviceable (it was made by Ferguson, and intended for cases of laryngotomy); on the convex surface of it is a groove (like a miniature staff), into which the point of the scalpel was inserted, and an incision in the bladder wall made direct from the point of puncture of the hook large enough to admit the finger. The stone was easily felt, and removed by means of a small pair of lithotomy forceps. A drainage tube was inserted into the bladder, but it slipped out during the night, and was not replaced. No sutures were placed in the walls of the bladder, but two in the upper part of the abdominal wound, which was dressed with absorbent cotton wool.

On the day of operation the evening temperature was 101°; next day, morning 100·4°, evening 101°; the following morning 99·6°, evening 100·4°. From this time the temperature remained about normal. There was a free discharge of urine through the wound. No catheter was passed until Jan. 25th, when a soft rubber one was tied in; this after the second day, however, set up urethritis, and was discontinued. The after treatment consisted in placing the patient alternately on one side or the other as much as possible, to encourage drainage. The wound was dressed with boracic lotion (1 in 80), and the urine absorbed by means of sponges and absorbent cotton wool. The patient's progress was satisfactory, but slow; the wound granulated, but cicatrisation took place slowly. On Feb. 6th (twenty-seven days from operation) twenty ounces of urine were passed through the urethra, being the first time it had flowed naturally since the operation. The abdominal wound now began to contract more rapidly. The stone was a mulberry calculus covered with phosphates weighing five drachms. The handle of the scalpel used was made of tortoiseshell rounded off at the end and bevelled to form an edge, and was admirably adapted for separating the tissues in this case.

WOLVERHAMPTON GENERAL HOSPITAL.

MULTIPLE ANEURYSMS OF THE ARCH OF THE AORTA.

FOR the following notes we are indebted to Mr. Arnold Evans.

R. L——, aged thirty-seven, grinder, having been seized with sudden illness whilst at work, was brought to the Wolverhampton General Hospital, but on arrival life was found to be extinct.

At the necropsy it was found that the pericardium contained about fifteen ounces of clotted blood. The heart, with the aorta and aneurysms attached, weighed about eighteen ounces. Apparently the aortic valve was competent, but its cusps were distinctly thickened. The ascending and transverse parts of the aortic arch were enormously dilated and thickened; and springing from the first part of the artery immediately above the valve were three aneurysms, each communicating with the artery by a narrow orifice: one sprang from the anterior surface of the vessel, and pointed downwards and forwards towards the origin of the pulmonary artery overlapping the appendix of the right auricle; the other two, each about the size of a walnut and situate close together, projected backwards under the aortic arch and compressed the pulmonary veins. One of these last mentioned had ruptured into the pericardium, forming an orifice which barely admitted the tip of the little finger, and had ragged and attenuated edges. About an inch higher up was a cluster of three aneurysms, each slightly larger than those above described, but resembling them in that each communicated with the artery by a narrow mouth; two projected forwards and the third to the right. Another aneurysm arose from the upper part of the arch; this was a little larger than the others, and had thin walls; from its side sprang the brachio-cephalic and left carotid arteries. There were several other small aneurysms in addition to those just described. All contained a small quantity of laminated clot. At the commencement of the descending part of the arch the aorta resumed its normal calibre, and in its onward course contained only a few small atheromatous patches. The mitral valve was competent, but its curtains were slightly thickened. The hypertrophy of the left ventricle was by no means great. There were no other aneurysms in the body. The only other morbid change in the organs was an œdematous condition of the lungs.

The most interesting point in connexion with the above case was the complete immunity (with the exception of a slight cough for a few days) from any serious or distressing symptom, until the time of the man's sudden death.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Multiple Neuro-fibromata and Molluscum Fibrosum.—Sarcoma of Pelvic Fascia.—Cerebral Hæmorrhage in a Child with Thrombosis of Sinuses.—Fibrous Contraction of Stomach.—Subpleural Lipoma of Diaphragm.—Rickets in the Skulls of Lions.—Suprapubic Abscess.—Cultivation Experiments with New Growths and Healthy Tissues, and the Parasitic Theory of Cancer.—Bones from Congenital Syphilis.

THE last ordinary meeting of this Society was held on Tuesday last, Sir James Paget, Bart., President, in the chair.

Mr. CHARTERS SYMONDS read the report of the Morbid Growths Committee on Mr. Hutchinson's specimen of Tumour of the Lower End of the Femur shown at the last meeting. The committee came to the conclusion that the morbid process was of an inflammatory nature, and most probably the result of syphilitic poison. Drs. Coupland and Payne and Mr. Bowlby were the other members of the committee.

Dr. F. J. PAYNE showed specimens from a case in which Fibro-Neuromata co-existed with Molluscum Fibrosum. The patient, a woman aged forty-three, had been under observation for some years as a well-marked case of molluscum fibrosum. The surface of the body was nearly covered with small, soft, fibrous tumours, from the size of a pin's head to that of a hazel-nut—some pendulous, some sessile, some under the skin. They had existed as long as the patient could remember. There was also a tumour, the size of a walnut, in the left axilla, formed on the brachial plexus; it gave rise to much nerve pain in the arm. It went on increasing in size, while the skin tumours varied, some new ones being formed, while others wasted and almost disappeared. During the last few months of life there was a marked diminution in their number. The patient died in August, 1886, with symptoms of violent summer diarrhœa. A partial necropsy only was possible, but all the chief organs were found healthy. The left brachial plexus was removed, and on dissection by Mr. Shattock there were found, besides the large tumour, a number of smaller ones, varying in size from a pin's head upwards, on various parts of the plexus, giving the appearance known as plexiform neuroma. These tumours had the usual structure of fibro-neuromata, consisting of nucleated fibrous tissue, in the midst of which the nerve-fibres could be traced. It was not possible to examine other nerves thoroughly, but the right brachial plexus appeared healthy. The skin-tumours, which were seated chiefly in the corium, but some in the subcutaneous tissue, consisted of fibro-nucleated tissue, the larger ones containing broad fibrous bundles with lacunæ. To ascertain the connexion of the tumours with the nerves sections were made by Mr. Shattock, and stained with osmic acid, as well as with other dyes; but though nerve-fibres were seen near the small tumours, none could be traced entering them, and the fibrous masses contained no nervous structures. At the same time, the possibility of the fibrous growths originating in the sheaths of nerves, as in the internal nerve-tumours, could not be disproved. These observations, therefore, only partially confirm those of Recklinghausen, who, in his classical memoir, "Die Multiplen Fibrome der Haut" (1882), first noticed in two cases the coincidence of fibroma molluscum of the skin with multiple fibrous tumours on the nerves, and explained the former as being neuro-fibroma of the skin.

Mr. LEOPOLD HUDSON showed a Sarcoma of the Recto-Vesical Fascia. The patient was a man twenty-eight years of age. There was no family history of tumour. The first symptom, seven months before his death, was pain on defecation, and on rectal examination a bilobed tumour feeling like an enormously enlarged prostate was found. Five weeks after its first appearance cutaneous nodules developed. The tumour grew rapidly, filled the pelvis, and extended upwards into the abdomen causing lancinating pains and severe vomiting. There was no albuminuria, and the constipation was overcome by purges. He died emaciated. At the necropsy the tumour was found to weigh seven pounds and a half, was distinctly encapsuled, and originated apparently from the layer of recto-vesical fascia which investing the vesiculæ seminales passes across the space between the bladder and the rectum. Examination proved the growth to be a small spindle and round-celled sarcoma, which had in part undergone development into a myxomatous tissue, and showed also areas of retrogression with mucoid cyst formation.—Dr. COLLIER mentioned a case in a young woman who, after a fall one month previously, experienced severe pain in the left iliac region, where a swelling formed, and there was considerable fever. Inflammation with caries was diagnosed, and an incision was made and much blood evacuated from the pelvis. The tumour proved to be sarcoma, and the specimen was shown. The total duration of the clinical course was apparently only ten weeks.

Dr. HANDFORD read a case of Cerebral Hæmorrhage in a boy aged five, following thrombosis of the venous sinuses. Drawings of the brain and preparations of the vessels of this case were shown. The chief symptoms had been headache, constipation, and frequent vomiting. There was no dryness or discharge from the ears. The breathing became stertorous three or four hours before death, which took place ten days after the commencement of the illness. There was no sign of head injury or disease of the ears. The venous sinuses were thrombosed, the superior longitudinal and lateral sinuses containing adherent decolourised clots. The superficial cerebral veins were also thrombosed, and felt like whipcord. There were numerous hæmorrhages on the surface of both hemispheres; two of them—viz., those in the left ascending parietal convolution and in the right temporo-sphenoidal lobe—being very extensive, and ploughing up the brain substance to a considerable depth. There was ground for supposing that the hæmorrhage occurred only a few hours before death. No cause for the thrombosis could be ascertained, neither could the ruptured vessels be

Digitized by Google

found. The cause of the hæmorrhage was assumed to be the increased vascular tension from the thrombosis of the sinuses; but whether the vessels that gave way were arteries or veins was left an open question, though Dr. Handford inclined to the latter view.—Dr. S. WILKS had seen five or six cases of thrombosis of the cerebral sinuses in young women suffering from severe anæmia, and in all there were hæmorrhages: the cause was probably in the blood.—Dr. COUPLAND had seen one case of thrombosis in the cranial sinuses in cancer, and he referred to Dr. Bright's paper on the subject.—Dr. ORD had seen thrombosis of the cranial sinuses in a case of acute rheumatism, in which phlebitis developed in the neck and arm on one side. There was hæmorrhage into the brain. Changes in the condition of the lining membrane of the vessels were perhaps operative in the causation.—Dr. T. BARLOW referred to the possible source of the hæmorrhage. In one case of a child who had marked anæmia and cachexia from whooping-cough and ulcerative bronchitis (bronchiectasis)—in all the cases he had seen there had been a long continued cachectic condition—there was a large hæmorrhage which might have proceeded from rupture of a large vessel, but there were innumerable small punctæ of hæmorrhage in the cerebral cortex, and the large hæmorrhage was probably a great mass of the small hæmorrhages. Sir William Jenner had told him that he considered the source of the hæmorrhage was the small venules, and was the result of the venous stasis.

Dr. CHARLEWOOD TURNER showed a specimen of Stenosis of the Stomach due to Fibroid Thickening; there was chronic ulceration of the anterior wall, but the whole stomach was seamed all over by fibroid tracts.

Mr. F. W. CLARK showed a Subpleural Lipoma taken from a woman aged sixty-five, in whom it had caused no symptoms. It was a lobulated tumour (lipoma) springing from the diaphragm and projecting into the right pleural cavity, without adhesions. Normally there was a growth of fat attached to the diaphragm on the right side anteriorly, and this outgrowth of fat from the diaphragm might go beyond the physiological bounds.

Mr. BLAND SUTTON made a communication on Rickets in Animals. The bones preformed in membrane were much thickened, and the diploë absent. The reverse of this process obtained in the cartilage-formed bones, they being very much thinned. The lions of Manchester and Dublin did not become rickety. Paraplegia developed in carnivorous rickets as the result of the epiphysial plates of the vertebræ becoming greatly overgrown. The tentorium cerebelli was enormously ossified; instead of being a thin plate of bone, it had become a veritable exostosis. Reference was made to the case of a cub which at two months of age became paraplegic. The tentorium was greatly ossified, and there was great dilatation of the cerebral ventricles as occurred in the brain in hydrocephalus, and due to interference with the circulation of cerebro-spinal fluid. Paraplegia was the first sign; then the head was drawn to one side and convulsions set in. Afterwards oscillation of the eyeballs and rhythmic movements in the head were observed. These symptoms were parallel to those described by Hilton, Wilks, and Moxon in cases of hydrocephalus in children.—Dr. HORROCKS asked why London lions developed rickets and not those in Dublin.—Sir JAMES PAGET said that Dr. S. Haughton had found that if bones were given to ricketty lions in Dublin the rickets disappeared. Had this been tried at the Zoological Gardens?—Mr. B. SUTTON, in reply, said that it was supposed that the constant use of horse's flesh was the cause of rickets, but even when goat's flesh was added and the bones could be eaten the rickets did not disappear. He could not offer any solution of the differences between lions in London and elsewhere. In reply to Sir James Paget he said that the giving the lions bones cured the cubs of being born with cleft palates, but did not prevent their developing rickets.

Mr. STEPHEN PAGET read a paper on Suprapubic Abscess, and showed one specimen removed from a man aged sixty-five, who had had cystitis and other bladder troubles, with a perforation leading obliquely into the cellular tissue of the pelvis. Cases of suprapubic abscess were not very common. Twenty cases were collected. Sixteen occurred in young or middle-aged men who were generally healthy and vigorous. Four occurred in women, after genital disease. In the males, eight under thirty and eight over this age. The inflammation resolved without suppuration in the cases under the age of thirty. Those that occurred after typhoid fever suppurated. Malignant disease was not noted in any case.

Mr. BALLANCE and Mr. SHATTOCK exhibited the results of a series of Cultivation Experiments made with New Growths. The authors were led to experiment with malignant new growths in this direction, since they were persuaded that the essential pathology of these must (as so greatly insisted upon by Sir James Paget) be similar to that of the specific diseases. Pieces of carcinomata of the breast removed immediately after operation and transferred to tubes of solidified serum, agar agar, and Koch's beef peptone gelatine, were incubated at 100° F. for various periods—in one case for thirty-three days. The authors compared the pathology of cancer with that of tubercle, and considered that cancer, like tubercle, might be either a purely local disease, or the local manifestation of a "diathesis," comparable to that of the "scrofulous," the localisation in either case depending upon a specific organism. The geographical distribution of cancer was also noticed as an argument in favour of its parastic nature. They met the chief objection urged against the parasitic theory—viz., that in a case of columnar-celled carcinoma of the rectum the secondary tumours in the liver resembled in structure the crypts of the intestine—by observing that in the normal process of development it is the epithelium that determines the anatomical character of glandular formation, the arrangement of vessels and connective tissue being a secondary adaptation to this; and they conjectured that in a similar manner a cell transported to another organ would by its determinate hereditary tendency produce a structure similar to that of which it primarily formed a part, the organ itself furnishing the vessels and supporting tissue of the new epithelial formation. They further remarked that the view of the parasitic nature of cancer afforded a possible explanation of the cachexia, which is at times not to be wholly accounted for on general principles, since all pathogenic organisms give rise, as a result of their activity, to deleterious chemical products, and these passing continually into the general circulation from the substance of the tumour would exert an unfavourable influence on the general health. The alleged antagonism of cancer and tubercle might be explained on the well-known grounds of the interference in growth which certain organisms exercise upon others. They concluded from their experiments that the parasite of cancer must be unlike in its life-history those already known, in that it does not admit of cultivation in any of the ordinary media. They commented upon the supposition that the parasite was one of the protozoa, and thought that the physiology of certain of the naked protozoa afforded much interesting material for speculation upon the physiology of cancer; the sporulation of protozoa and the rejuvenescence by fusion were referred to as offering possible modes of explaining the infection of the epithelium, the abnormal growth and extension of which constituted the characteristics of carcinoma. Having found that new growths were sterile under the conditions of the experiments, the authors experimented in a similar way with healthy tissues, with the result that they were able to maintain sterile at 100° F. portions of testicle, submaxillary gland, kidney, muscle, and liver. In regard to the liver, they were not prepared to state that the same holds good, since in most cases the portions experimented with did not remain sterile. These results accord with Mr. Watson Cheyne's previous work reported in the Society's Transactions for 1879.—Dr. COUPLAND said that the late Dr. Grant believed that white corpuscles of the blood were forms of the lowest protozoa.—Mr. F. S. EVE gave arguments against the parasitic theory. He had repeated Leopold's experiment and transplanted portions of epitheliomata of the tongue into the anterior chamber of the eye of the rabbit, and acute suppuration followed, although it was known that this chamber was very tolerant of living tissues.—Mr. ROGER WILLIAMS also combated the parasitic theory.—Mr. FELIX SEMON referred to the antagonism alleged to exist between tubercle and epithelioma. He had seen the two forms together in the larynx.—Mr. S. PAGET referred to a paper in THE LANCET of May 14th by Mr. Roger Williams.—Sir JAMES PAGET said that he had known cancer almost decay and shrivel up during the rapid development of tubercle, and *vice versâ*; neither lived in full force together. He felt that he must have made a happy guess in early life, and he thought that very likely the parasitic theory would be found to give an explanation of the great difference between innocent and malignant growths.—Mr. BALLANCE said he could not imagine any other result than suppuration following the inoculation of material from any growth on

Digitized by Google

any surface of the body. They did not believe that the parasite was a bacterium.—Mr. SHATTOCK, in reply, said that he imagined that the transported cell was provoked to multiply by the irritation of the contained parasite.

Mr. W. H. BATTLE showed specimens of Extensive Bony Lesions from Congenital Syphilis and Rickets. The illegitimate child was three years and ten months old. One year before admission the left elbow swelled, and afterwards the right one, and then the right knee. Progressive emaciation, sleeplessness, and great tenderness were the chief symptoms one month before death. There was also considerable fever —101° to 103° F. The necropsy showed broncho-pneumonia and collapse of the lungs. There was separation of the epiphysis from the diaphysis of the femur, the periosteum was separated from the shaft over nearly the lower half, and was much thickened and vascular, with slight new formation of bone. The tibia showed a similar necrosis with separation of epiphysis. There were similar changes in the bones of the upper extremity, with signs of rickets in the ribs and about the growing ends of the shafts of the bones. There was marked "bossy" growths on the skull, which had a natiform aspect.

The following card specimens were exhibited:—Mr. Page, for Mr. Raven: Sarcoma of Dorsal Vertebræ. Mr. Sydney Jones: 1. Tumour of Parotid, twenty-five years' growth. 2. Papilloma of Bladder removed by Suprapubic Cystotomy. 3. Uterus and Appendages extirpated for obstruction of rectum and bladder. Dr. Barlow: Renal Sarcoma. Dr. Pitt: Pleura, two years after drainage for Empyema. Dr. Collier: Pelvic Sarcoma, simulating Hæmatocele during life. Dr. C. Turner: 1. Bladder, Kidney, and Dura Mater, from a case of Purpura. 2. Endocarditis, with Necrosis of Mitral Valve. Mr. J. H. Morgan: Cystic Disease of Metatarsal Bone. Mr. Fenwick: 1. Encephaloid Cancer of Apex of Bladder. 2. Acute Tuberculosis of Bladder and Prostate. 3. Purpura Hæmorrhagica of Bladder. Mr. Bull, for Mr. Rouse: Sarcoma of Clavicle. Mr. Mansell-Moullin: 1. Abscess of Brain following Disease of the Ear; trephining. 2. Sacculated Bladder, with Calculus impacted behind the Prostate. Mr. Poland: Osteomyelitis of Scapula and separation of Coracoid Process. Dr. Gulliver: Aortic Aneurysm opening into Superior Cava. Mr. Targett: Bony Tumour of Buttock. Dr. Hebb: Quiescent Tubercle (a Disseminated Fibrosis) of Lung. Dr. Horrocks: Uterus and Fibroids removed by Abdominal Section (recent specimen).

CLINICAL SOCIETY OF LONDON.

Abdominal Cysts following Injury.—Spasmodic Torticollis due to Cerebral Lesion.—Gouty Knee-joint with Suppuration.—Intracapsular Fracture of Neck of Femur.

AN ordinary meeting of this Society was held on the 13th inst., Dr. W. H. Broadbent, President, in the chair.

Mr. GODLEE related three cases in which abdominal cysts of large size followed the passage of a cart wheel over the body of the patient. The first was a little girl aged four, who sustained a rupture of the left ureter. A large cystic tumour containing urine developed itself, which was first aspirated and then tapped and drained. The kidney was felt projecting into the upper part of the cavity when it was opened. As the patient became liable to frequently recurring attacks of fever, caused by accumulations of urine and pus at the bottom of the wound, it was decided to remove the kidney, which was accordingly done. The operation was a difficult one, but the child made an excellent recovery. The sinus, however, has not completely closed, but still continues to secrete a small amount of pus. The second case was that of a man aged twenty-three, who was run over by a heavy waggon. A cystic tumour developed itself on the left side, partly under the ribs, partly projecting below them, causing considerable discomfort and vomiting. After periods of improvements and relapses the tumour was aspirated through the seventh intercostal space, and seven ounces of turbid fluid, containing a trace of urea with a considerable amount of albumen, were drawn off. After this the patient gradually recovered. It was pointed out that, while the diagnosis of the case was very obscure, it was probably a renal cyst resulting from a laceration of the kidney. The third case was that of a boy aged seven, who was knocked down by a van, but not run over. A month afterwards, a tumour of considerable size, but the dimensions of which apparently varied, was found in the upper part of the abdomen on the left side. During the eleven months after the accident the tumour gradually increased in size, and came to occupy the middle line of the abdomen, pressing the stomach upwards. It was accordingly opened, and the cyst wall was stitched to the abdominal wall. It contained forty-three ounces of turbid whitish-yellow fluid, containing five ounces of urea and a large amount of albumen. The child made an excellent recovery. There appeared to be no data for making a diagnosis in the case.—Mr. GOLDING BIRD said that urea might be found in appreciable quantities in most of the tissues and fluids of the body, so that its presence in minute proportions did not necessarily indicate a connexion with the kidney. He had found as much as ·2 per cent. in ovarian fluids.—Mr. BARKER referred to a case of his own, published in THE LANCET, Jan. 17th, 1885, in which ·5 per cent. of urea was found. This low percentage appeared to be due to reflex pressure on the kidney, for on opening the cyst the percentage rose to more than 1 per cent. A second case was alluded to, in which the patient having been run over, the abdomen began to swell greatly. After some months forty-five ounces of fluid were withdrawn from a point three inches to the left of the middle line; the fluid contained a considerable quantity of urea. The case was probably a localised peritonitis, and not a renal tumour. The presence of urea should not therefore in itself suggest a renal origin for the cystic tumour.

Dr. G. V. POORE read a case of Spasmodic Torticollis, probably caused by Cerebral Lesion. The patient, aged thirty-six, was admitted to University College Hospital on Aug. 5th, 1886, suffering from violent spasmodic torticollis of nearly six months' duration. The head was twisted towards the right shoulder. At first the left sterno-mastoid muscle was mainly at fault, but after division of the sternal attachment of this muscle the spasm was scarcely altered, the rotation of the head being effected by the right splenius. This fact made it probable that the lesion was central. On the left side of the head, immediately over the situation of the posterior part of the superior and middle frontal convolutions, was a scar, the result of an injury many years previously, which at the time had "half-stunned him." There was an undoubted history of syphilis, and the patient, prior to the onset of the torticollis, had suffered from headache, referred to the neighbourhood of the scar, and from occasional attacks of giddiness. All things considered, it seemed probable that the lesion (? meningeal thickening) would be found on the surface of the brain beneath the scar on the scalp—i.e., in the region irritation of which is said to cause deviation of the head to the opposite side. The propriety of trephining was considered, but prior to its performance it was deemed advisable to subject the patient to a thorough course of mercury. This was done, with the result that the torticollis almost completely disappeared.—Mr. B. ROTH asked whether the spasm disappeared when the patient was under the influence of chloroform.—Dr. GLOVER spoke of the extreme severity of the spasm. The case showed the virtue of patience in physicians before calling in surgical aid.—Dr. S. MACKENZIE mentioned Dr. Ringer's case, shown to be associated with a lesion about the ganglia of the brain; and also referred to the case of Mr. Campbell de Morgan, in which the spinal accessory nerve was stretched with success. In other cases various operations were undertaken without success, and the arm and other parts of the neck were sometimes involved.—Dr. BROADBENT alluded to the hemiplegic lateral deviation of the head and eyes, and said that the cortical mechanism must be similar in Dr. Poore's case. The higher centre calls upon and commands muscles on opposite sides of the body, as in conjugate palsy of the eyeballs. The deviation disappears as soon as communication is established with the opposite cerebral hemisphere. Permanent deviations are present when there is a lesion in the medulla. He had no doubt of the correctness of the localisation, and the striking development of symptoms during the waking state was very confirmatory, as also the relaxation during sleep.—Dr. POORE, in reply, said that the difference observed during the waking and sleeping states went to prove the cortical origin of the spasm, so he did not give the patient chloroform, because natural sleep sufficed. He had made a bare recital of one isolated case, and had not weighted his paper with literature. Cases which had preceded or followed hemiplegia were well known, and also that mercury had relieved other cases. He considered that trephining would be warrantable, for the danger of the operation was slight.

Digitized by Google

Mr. STEPHEN PAGET showed a Knee Joint from the body of a man, aged forty-nine, who had suffered for seventeen years from severe gout. The knee was suddenly attacked by acute inflammation, and a very large abscess occupied the joint and the thigh. It was aspirated, and perfectly healthy pus was let out; later it was opened. Suppuration extended up nearly to the trochanter and down into the calf; and several counter-openings were necessary. Amputation was not advised, on account of the constitution being broken down by disease. For some time he seemed likely to recover, but at last bedsores formed, and he died about eleven weeks after the invasion of the inflammation. The specimen showed destruction of the cartilages and ligaments, with rarefaction of the ends of the bones; no marked lipping or eburnation. The synovial membrane was infiltrated and partly destroyed by suppuration. Mr. Paget referred to a case published by Dr. Norman Moore of purulent effusion into the knee joint in chronic gout, a case of suppuration of the back of the hand and the wrist joint published by Mr. Rivington, and a case of suppuration of the eyeball published by the late Mr. Critchett. In all these cases the only common cause for the suppuration was chronic gout, of very long duration and of great severity.

Mr. SPENCER WATSON read notes of a case of Intra-capsular Fracture of the Neck of the Femur, with specimen. A gentleman aged sixty-nine fell from his horse, and on attempting to rise found he could not support himself on his right leg. There were no symptoms of fracture, beyond the pain on attempting to move the limb for a fortnight after the accident, and measurements taken several times during the period indicated no shortening. Three weeks after the accident shortening of the right limb to the extent of an inch and a quarter was discovered. No splint or extension apparatus could be borne by the patient, who got up and sat in a chair from the first week, and was on crutches at the end of a month. He died seven months after the injury, and the specimen exhibited showed a fracture through the neck of the femur, intra-capsular, and at one time firmly impacted. The neck of the femur was so much wasted that the head of the bone rested on the space between the two trochanters, and was kept in that position by interlocking splinters of the neck.—Mr. WM. ADAMS said that in intra-capsular fracture a difference existed in the degree of mobility and shortening in different cases, dependent on the kind and direction of the fracture. If the fracture were oblique and irregular, a sort of impaction might have taken place, and yet the diagnosis of fracture be doubted. In the specimen shown the periosteum had become folded in between the fragments, and a neoplasia of fibrous tissue afforded a very fair fibrous union.—Mr. CHRISTOPHER HEATH said that measurement might detect slight differences in the length of normal limbs, and much importance could not be attached to slight differences as indicating fracture. If the patient could raise the limb, then the fracture must necessarily be of the impacted sort.

The following living specimens were exhibited:—Mr. Clutton: Osteitis Deformans in a woman. Dr. Percy Kidd: Rheumatic Nodules in an old woman. Dr. de Havilland Hall: Adhesion of Soft Palate to Posterior Wall of the Pharynx. Mr. Mansell-Moullin: Elephantiasis of Right Leg.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

Some Evidence respecting Tubercular Infective Areas.

AT a meeting of this Society held on Wednesday, May 11th, Inspector-General Lawson in the chair, Dr. ARTHUR RANSOME read a paper on some Evidence respecting Tubercular Infective Areas. He showed that there are strong reasons for believing that whilst tubercle travels infectively through the body, and is derived from infective particles contained in air rendered impure by organic matter from human breath or from ground air, yet it is very rarely directly transmitted from person to person. It seems most probable that for the active propagation of the disease some increase in the virulence of the organism must take place outside the body, in a manner similar to the infection of typhoid fever or cholera. Although direct transference of the complaint is probable, especially after previous injury and loss of elasticity of the lungs, yet the evidence so far adduced would seem to show that it is a very rare event—first, because many medical men have never seen a case; secondly, many of those recorded as cases of infection would have taken place without infection, as shown by Dr. Longstaff's formula; thirdly, most of these cases of supposed infection lived under conditions favourable to indirect infection; fourthly, it is difficult to see why drainage of the land and the sandy condition of a soil should affect direct contagion, but it is easy to see why indirect infection should be thus affected; fifthly, the frequency of one-sided phthisis was pointed out. Numerous instances of infected areas were given from records of barracks, public institutions, ships, &c., and cases of infected houses were given from private practice from the Collective Investigation Record and from other sources. In all of these the outside conditions as to ventilation, drainage, soil, &c., were favourable to the intensification of the virulence of the morbific agent. The mortality tables of certain districts in Manchester and Salford had also been kindly given to the author by the medical officers of health, Mr. Leigh and Dr. Tatham; and maps showing the construction of the Salford districts had been furnished by Dr. Tatham. An analysis of these showed that in certain streets and courts, consisting of back-to-back houses, and with no through ventilation, the disease was much more common than in other parts; and that it occurred again and again in the same house in these parts. In all, forty-one cases of such coincidence of death were detected in five years in Ancoats in a population of 5600; and in Greengate, Salford, with a population of 2600, in six years, there were twenty-nine such double or treble deaths. Certain possible sources of fallacy were discussed. In the discussion which followed, Inspector-General Lawson, Brigade Surgeon Scriven, Surgeon-Major Pringle, Dr. Moir, and Messrs. Paget and Murphy took part.

MEDICO-PSYCHOLOGICAL ASSOCIATION.

THE quarterly meeting of the above Association was held at Bethlem Hospital on Tuesday, May 17th, the principal business being to consider a memorandum from the Parliamentary committee of the Association containing observations and suggestions in regard to the Lunacy Acts Amendment Bill. In the absence at first of Dr. Savage, Dr. Rayner occupied the chair. A long discussion ensued, in which Drs. Ringrose Atkins, Outterson Wood, A. R. Urquhart, J. Murray Lindsay, S. W. D. Williams, Hayes Newington, Hack Tuke, G. H. Savage, H. Rayner, S. H. Agar, Robert Baker, and Evan Powell took part. In opening the discussion, the chairman animadverted upon some observations made by the Lord Chancellor in introducing the Bill, and to his having made use of certain words, i.e., "accused" of lunacy, "supposed" examination, &c, which, if lightly construed, associated lunacy with crime, and further implied perfunctory work or laxity on the part of medical men in their professional duties in connexion with lunacy. Suggestions having been freely made on the various clauses of the Bill, it was agreed that the memorandum should be circulated among the members of the Association, now numbering upwards of four hundred. A strong opinion appeared to prevail that the magisterial intervention proposed by the Bill should not be allowed entirely to override medical opinion, and, further, that there should be a power of appeal to the Home Secretary in cases of refusal or reduction of pensions. It was also urged that members of the Association should seek to impress most earnestly on members of the House of Commons with whom they were acquainted that insanity is a symptom of disease, and that the primary aim and object of all legislation in regard to it should be the care and proper treatment of those suffering from it.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Empyema.

AT the ordinary meeting on April 1st, Dr. Spottiswoode Cameron, Vice-President, in the chair, a discussion took place on the above subject.

Dr. CHURTON cited some remarkable examples of empyema, selected from seventy cases, in some of which the pus was difficult to find, and in others there had been difficulties in the operation required. He also described cases of double and of fetid empyema, and of apparent empyema in which the pus came from dilated bronchi.—Mr. GODFREY CARTER

Digitized by Google

described the case of a girl in whom symptoms of pneumonia on the left side were followed by symptoms of dyspnœa and signs of fluid in the opposite side. Some days afterwards pus was evacuated by incision, but no great improvement followed. Three exploratory punctures were made in the first affected side without effect; but in a month's time, dyspnœa being urgent, repeated exploration was made under chloroform, and pus was found on the left side in the eighth space near the spine. As the right side seemed nearly healed, and only a few ounces of water could be injected, an incision was made in the left side and a large quantity of pus evacuated, with satisfactory result. — Dr. WARDROP GRIFFITH gave statistics of thirty-three male and seventeen female cases treated in the Leeds Infirmary. 1. As to age: Twenty-nine were in the first decade, seven in the second, and eight in the third. Contrasting these with a similar number of cases of simple effusion, there were ten in the first decade, sixteen in the second, and nine between thirty and forty, against one only of purulent effusion. 2. The right side was affected in nineteen; the left in twenty-six; both in one. 3. As to results: Thirty-five cases recovered after incision. In four of these there was certain or suspected phthisis; five cases, in addition, were discharged with a sinus still open. 4. Six cases were fatal, three from advanced phthisis. In one there was double effusion, and another was complicated by hepatic abscess. 5. There was a history of injury in three instances. In most cases the fluid seems to have been purulent from the beginning. Out of 151 cases of simple effusion treated in the infirmary, of which most were tapped, only two became subsequently purulent, suffering respectively from tuberculosis and erysipelas. 6. Physical signs: There was œdema of the chest wall in one case only. In children there was great deviation from the physical signs, vocal fremitus being frequently marked, and considerable effusion being present. 7. The operations were done mostly under ether, which the patients took well. The spray was used, and the incision was made low down at the back. No ribs were excised, although in two cases this might have been done with advantage. In nine cases there was pointing of pus, a spontaneous opening in four, and in one case the pus pointed behind.—Dr. CLIFFORD ALLBUTT held that resection of ribs was never needed if the operation was done early enough. All effusions of any bulk should be promptly and repeatedly removed. If the case were uncomplicated, and the operation and drainage efficient, the temperature should never be raised. Injections were therefore worse than useless.—Mr. MCGILL referred to a case where a piece of drainage-tube remained in the chest four years; it was removed post mortem.—Mr. LITTLEWOOD described a case where he accidentally penetrated into the peritoneum. The incision was made in the eighth space, extending as far forward as the mid-axillary line. Omentum was seen in the anterior part of the opening.—Dr. EDDISON referred to the statistics of forty cases under the care of Dr. Allbutt, Dr. Churton, and himself, which he had published three years before. The largest proportion of his cases occurred between the ages of twenty and thirty. In one case there was reason to believe the effusion had existed for three years, in another for one year; both recovered. In one case, where 150 oz. of pus were removed, death ensued within fifteen minutes. Cases with 62 oz. and 104 oz. removed recovered. In no case did death occur if the lungs were healthy. He had never seen a case where resection of the rib was necessary. — Mr. LAWFORD KNAGGS spoke against the use of anæsthetics, preferring cocaine.—Dr. TEMPEST ANDERSON recommended a double opening made with a curved trocar.—Dr. CHURTON, in reply to Dr. Allbutt, said he had known cases where the temperature remained high for some days after operation in spite of perfect drainage, but was reduced by five grains of quinine three times a day.

Pathological specimens.—Mr. L. Knaggs: Dermoid Cyst of Broad Ligament. Dr. Allan: Rupture of the Bladder from Retroversion of Gravid Uterus, which had become occluded by adhesions. Mr. Mayo Robson: (1) Polycystic Ovary; (2) Uterine Appendages removed for rapidly-growing Fibroid of Uterus. Dr. Braithwaite: Uterus with Cylindrical Cancer, removed by Vaginal Hysterectomy. Dr. W. Griffith: (1) Thoracic Aneurysm, showing thick Laminated Clot; (2) Case of Extreme Aortic Stenosis without Incompetence; (3) Microscopic Sections of Tubercular Tumour of the Optic Tract, causing Hemianopsia. Dr. E. Jacob: Sections and Microphotographs of a Sporosperm of Coccidium Oviforme from the liver of a rabbit, the bile-ducts being greatly dilated and a condition resembling encephaloid [illegible].

Reviews and Notices of Books.

Pilocereus Senilis, and other Papers. By WALTER MOXON, M.D., F.R.C.P. London: Sampson Low and Co. 1887.

THIS little volume consists of short essays contributed to the *Guy's Hospital Gazette* under the assumed title given above, together with three longer essays, two of which are introductory or annual addresses. We have read it through from cover to cover, and with much enjoyment. No book more vividly recalls its author; his keen, eager face, his eyes twinkling with humour, and his body with its curious, sudden movements (we often wonder who was the originator of the Guy's Hospital gestures), rise up before us as we read. The author being, in this instance, identical with his book, we may speak of either indifferently. The prevailing element in his writing is humour—searching, keen, and critical, but always good-natured. When he incites us to laugh at an individual, he always invites the subject of laughter to join with us; he says as plainly as words can speak, "Let us all laugh together." We have heard that this habit of his sometimes gave dire offence to students, but no statistics are forthcoming as to the part of the United Kingdom from which such individuals sprang. Another element in his humour which adds greatly to its value is his essentially reverent treatment of great questions, which is very striking. We often seem to enter quite suddenly from the light and glitter of clever banter into the dimness and quiet of a sanctuary. The literary effect of this is not inconsiderable, but its moral effect is greater still. We can quite well understand that these qualities, which charm those who are sympathetic, may have narrowed the circle of his disciples; but even those who failed to follow his meaning cannot have been entirely unaffected by his purpose.

The essays themselves are not, indeed, easy reading. To read easily, the mind of the reader must travel with the writer, and be not altogether unprepared for the next sentence. For this to be possible the motion of the author must generally be rhythmical, like the flight of a bird. But in reading these essays we are reminded of nothing so much as of a dragon-fly on a brilliant summer afternoon, glittering with gold, and barred with stripes, which is seen fluttering near; anon he has disappeared, and again reappears some distance off, and again he is gone. The glitter rivets the attention; the sudden darts cannot be followed, but we cannot but gaze and admire. Of the essays, we like the short ones best of all, where all are good, none more than that with the Guy's Hospital motto, *Dare quam accipere*. It is pleasanter to give than to receive medicine prescribed in the surgery (why *is* it made so nasty?), advice, and even money sometimes. The division of advisers (p. 11) into the sympathetic, apathetic, and antipathetic, is admirable. The first says, "Let me help you?"; the second, "Do as you like"; the third, "Get thee and hang thyself." The first, in the case of a bad tooth, will say: "Let's see if stopping will do any good." The second: "Now then, if you're going to have it out sit down." The third drowns the enemy's yells with "Don't make that noise, it doesn't hurt you." "The thoughts of the heart" is another which is itself full of thought. Thoughts are not only of the brain, as physiologists say. "The fact is, the brain is a sort of Æolian instrument of many strings, whereupon the several organs play (notably those of the circulation—the heart), and so David was right." "Special kinds of activity determine character. Thus are we creatures of our own activities, and he who has no special activity will have no character." We have not room for all the passages we should like to quote; but we must select a few to whet our reader's appetite, and make him long for more.

'Why cannot we combine against the continual heaping

Digitized by Google

up of unverified hearsay? Ingenious men with large memories connect together various well-meant quotations, until some far-away propositions, uncertainly drawn from uncertain sources, go for the 'progress of medicine.'" (Page 34.)

"Did you ever see a caddis worm? When I was fishing I never could stick a hook into a caddis worm. I never contemplate a caddis worm without a certain feeling of brotherhood. Nature is essentially too satirical in the way she takes off one thing when she designs another. Every one has, by nature, the faculty of picking up bits wherewith to furnish himself according to the grounds he is upon at the time, as the caddis worm dresses herself in scraps of green when she is upon leaves, and in bits of brown when upon the stones.....Most minds are like maggots dressed in scraps, and all that is their own is just the glue the scraps are stuck with.....You mustn't shake the scraps much for fear you see the maggot." (Page 42.)

"With one man faith may be compared to wings supporting him by his own brave effort where there is no ground to stand upon, and with another, faith is as a prehensile tail, such as you see on those monkeys who, holding securely by something they are not obliged to keep in view, have their hands thereby the more free to pick nuts, &c. Let us not think disrespectfully of any; to the born prehensile such a tail is a requisite. We see how needful it may be at the 'Zoo,' and though nature gives the human form no such outward and visible sign of dependence, it may be just the same inwardly with men." (Page 44.)

"I have met the modern scientific and well-read youth, who has studied chemico-physiological lectures upon texture and its vitality until he thinks that the life is nothing more than meat, and read Carlyle's 'Sartor Resartus' until he suspects 'nor the body than raiment,' and who would call the holding of such opinions 'faith,' and then wonder at the enthusiasm faith has aroused in the world." (Page 46.)

"No thought is ever strong and true which does not arouse something into unexpected harmony." (Page 70.)

"It (the present classification of diseases—one a pain in the leg, another a growth in the stomach, and another a spider in the skin) is like trying to mix the solar spectrum and the key of C major with essence of peppermint." (Pape 89.)

"Some day, you know, we shall be historic ourselves; that is, the louder ones amongst us—a chastening thought, when you reflect what sort make the most noise." (Page 125.)

On page 138, treatment without drugs is compared to religion without a creed. "It is very sublime, and suits your inside nature so well that you try it on your friends; but it does not suit them."

"Patients do not drink medicine as medicine. They swallow it as if to Æsculapius, and in the gulp their eyes sparkle with all the old ineffaceable longing for help from the unknown. The time-honoured potion carries with it the undying power of the medicine-gods and medicine-man of fairyland, and of the witches as real as ever." (Page 147.)

A few pages further on the author discusses homœopathy excellently, but we have not space for all the quotations we should like to make.

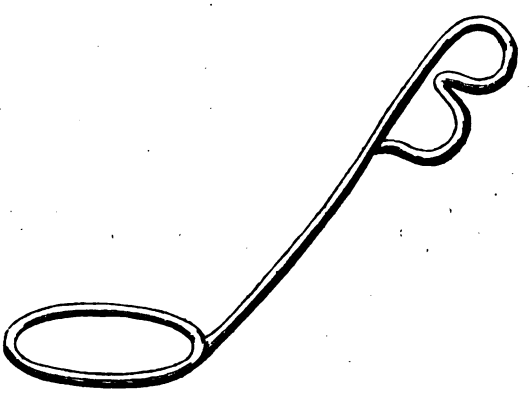
"The great fallacy of the age is the vulgar fallacy that 'Knowledge is power.' But not all knowledge is power. Only the knowledge you have faith and aim to use is power." (Page 205.)

"The power of knowing is the fruit of knowing, and the power of acting is the fruit of acting." (Page 206.)

"If we follow the biologist through his long story, what does he do towards touching the mystery of genesis, or help us to conceive how a little thing shaped like a frying-pan, and so small that you can scarcely see it with the best microscope, shall carry over the shape of the paternal nose, the colour of his whiskers, and even his mode of thinking, for sixty odd years?" (Page 216.)

"We want less of such biology as takes all purpose out of the universe and aims at professing a theology of high apes.....But Hunter's back was towards all apes, and his face to the future, because he did not make futile biology, but took pains to bring in the knowledge of nature to the help of man." (Page 222.)

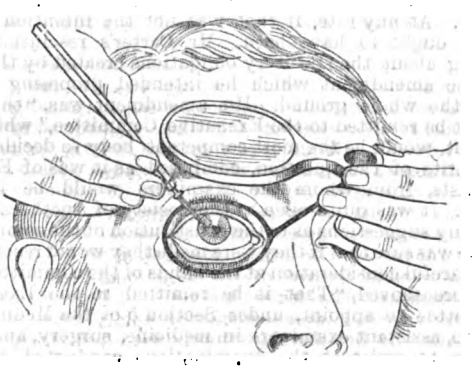
From the suggestive essay on "Alcohol and Individuality" we have not space to quote.



The foregoing quotations sufficiently illustrate our author's aptitude for epigram, love of paradox, and humour. He strikes us as the type of man who generally gravitates to the Bar. Such powers fill the pocket better in the legal profession, but their possessors are not always the better for such a choice, and we are thankful for the choice made by Dr. Moxon. Indeed, the profession can ill spare such men, and to his school his loss must be irreparable.

New Inventions.

A NEW EYE SPECULUM.



THE ordinary speculums are perfectly efficient in exposing the eyeball, but as they all have some part which enters within the margin of the eyelids, their use is necessarily attended with discomfort to the patient, which in slight operations, such as removal of foreign bodies from the cornea, or puncture of the cornea, is often more than the pain of the operation itself. For such cases the author has used the speculum shown in Fig. 1 for several years, and now brings it under the notice of the profession. It consists of

FIG. 1.

a piece of stout wire bent into an oval ring at one end and a handle at the other, as shown full size in the figure. Fig. 2 shows on a reduced scale the mode of application for removing a foreign body, the operator standing behind the patient's head. The ring is applied outside the lids and near their edges. The lids are then, if necessary, pulled more open by the fingers of the other hand. The pressure of the speculum gives it such a good hold on the skin that

FIG. 2.

even the most intense spasm of the sphincter is powerless to close the eye. The pressure to a great extent fixes the eyeball, and also renders the cornea tense, which is a great advantage, especially in puncturing the cornea. In removing a foreign body it is usual and perfectly easy to hold a magnifier in the same hand as the speculum, but this may be dispensed with if preferred. Messrs. Wood and Co., of York, are the makers.

THE GENERAL COUNCIL OF MEDICAL EDUCATION & REGISTRATION.

FRIDAY, MAY 13TH.

MR. MARSHALL, PRESIDENT, IN THE CHAIR.

MR. CARTER'S motion with reference to the appointment of examiners to the Society of Apothecaries was adopted without further discussion.

In pursuance of the proposal made on the previous day,

MR. CARTER moved the appointment as assistant examiners to the Society of Apothecaries of Messrs. Makins, Walsham, and Andrew Clark, and, referring to the point raised by Mr. McVail as to whether the Council could appoint more examiners than were asked for by the Society, said he thought they could not do so, though he admitted that those who were nominated by the Council would carry with them peculiar authority, and if they were of opinion that examinations were not properly conducted the Council would be able to interfere and make a statement to that effect to the Privy Council. Irrespective of the legal aspects of the question, he would suggest to the Council whether it would not be better simply as a matter of courtesy to afford every assistance that was asked of them. The Society desired that those gentlemen who had been appointed surgical examiners in accordance with the recommendation of the Council should be confirmed in their position, although it was fully recognised that if the Council's nominees were accepted they would be empowered to exercise an influence in excess of that of the ordinary members.

The motion having been seconded by Mr. SIMON,

MR. MACNAMARA remarked that it had been stated by Mr. Carter that it was necessary that the responsibility of examinations should rest entirely with the body which he represented. What, then, became of the Medical Council? The Act of Parliament had cast the responsibility upon the Council, and by its action on the previous day the Council had accepted that responsibility. The Act distinctly stated that it was the duty of the examiners to maintain the standard of efficiency in medicine, surgery, and midwifery, and clearly there ought to be an examiner to report to the Council upon the examinations on the last-mentioned subject. As showing the necessity of this, he might say that, though he considered himself a very good surgeon, he had only delivered two women in the course of his life; how, therefore, could he be expected to sit in judgment on midwifery examinations? Such an official would not exclude the Society's examiners, but co-operate with them. The same observation would apply to examinations in medicine and surgery; in fact, he thought the Council might supplement the Society's Court of Examiners by adding, if necessary, an examiner in connexion with the subjects of surgery, medicine, and midwifery. At any rate, if that was not the intention of the Act it ought to have been. Mr. Carter's resolution said nothing about the statutory obligations created by the Act, but the amendment which he intended proposing would cover the whole ground. His amendment was, "that the subject be remitted to the Executive Committee," which, he thought, would be the most competent body to decide upon the merits of the question, composed as it was of English scientists, from whom the examiners would be largely drawn. It was quite open to the Society of Apothecaries to offer any suggestions as to the constitution of the committee, and he was sure that if they were made they would receive the most careful consideration at the hands of the committee. He therefore moved, "That it be remitted to the Executive Committee to appoint, under Section 5 of the Medical Act of 1886, assistant examiners in medicine, surgery, and midwifery, to assist at the examinations conducted by the Society of Apothecaries in London, and to fix the amount of remuneration to be paid such examiners by the Society of

[illegible] having seconded the amendment,

[illegible]

believed that it should simply provide for a recognised deficiency in the examining powers of the corporation.

SIR WM. TURNER having directed attention to the wording of Sub-section 2 of Section 5 of the Act,

SIR WALTER FOSTER observed that he could not vote for Mr. Carter's resolution because he feared that, if carried, it would in the future place the Council in a dangerous position. Any action that they might now take would become a precedent, and the question before them ought, therefore, to be discussed with great deliberation. He looked upon the Council as the supreme authority for the regulation of medical examinations, and consequently it was not in the power of any of the corporations to dictate the course of procedure which it should adopt. The Council had affirmed by resolution the principle that the Society of Apothecaries was entitled to hold a qualifying examination, but when the latter endeavoured to nominate examiners the effect was to make the Council a body for registering their degrees, and that position could not, of course be accepted. The Act of 1886 regarded the Society as capable of holding an examination, not in surgery, but in medicine and midwifery, and it gave the Council a discretionary power to remedy this deficiency by appointing any number of examiners they thought fit in order to make each body complete in itself. It was not contemplated that the Council was to send to the Apothecaries' Society additional examiners in medicine and midwifery, because those subjects were already admitted to the Register, so that there was no necessity to interfere with what was already declared to be right and proper; all that it was necessary to do was to intervene in connexion with the surgery examination, and make it of such a character as to meet with the approval of the Council. Mr. Macnamara's amendment sought to authorise the appointment of examiners in three subjects, and to that he (Sir Walter Foster) could by no means consent, as it was not contemplated by the Act. He would suggest that in order to enable the Executive Committee to report on the matter further debate should be postponed.

DR. PETTIGREW argued that the Council would not carry out its duties if it simply appointed additional examiners in surgery, seeing that it was their province to maintain the standard of efficiency in medicine, surgery, and midwifery.

MR. MCVAIL, after observing that if such a committee as had been proposed were appointed the difficulty might perhaps be evaded, proceeded to point out that the Act declared that certain universities were still able to hold qualifying examinations, and that if other bodies deficient in such powers were unable to combine with those that were thus privileged they might join with the Council whose examiners would have the power of controlling the examinations. The Council were now in a position to form a union with the Apothecaries' Society exactly as the College of Surgeons might have done had it been so minded. Such examiners, however, would not merely be responsible for surgery, but for medicine and midwifery also, because the Act expressly mentioned that this should be done. It was imperative on the Council to carry out the provisions of the statute, and it was useless to attempt to wriggle out of an obvious duty simply because it might be urged that the Act was badly drawn. Mr. Carter had succeeded in joining his Society with the Council, and he ought to be proud of it, but if his proposals were accepted he would do harm to the institution with which he was connected, and help to render the Act a farce and a sham. He agreed with Sir Walter Foster that it would be better to delay further discussion until they realised their exact position.

MR. CARTER said he was willing to withdraw his motion, but announced that he would vote in favour of the amendment which Sir W. Foster proposed to bring forward in preference to supporting that which Mr. Macnamara had submitted.

SIR W. GULL, after expressing the satisfaction [illegible] being born this side of the Tweed, went on to [illegible] he had not much logic, he possessed some common [illegible] McVail had supplied them with no end of [illegible] all ended in wind. (Laughter.) It had been [illegible] Council that the Society of Apothecaries should [illegible] ying examination, and they were now asked [illegible] Society to carry that examination to the [illegible] the suggestion made by Mr. McVail that [illegible] should appoint examiners in all sorts of [illegible] saying, "Why make your bridge [illegible] The Apothecaries' Society could not examine

Digitized by Google

it naturally came to the Medical Council for the necessary powers; but it seemed that if Mr. McVail could have his way he would extend the provisions of the Act to all space and time, even to the controlling of the movements of the heavenly bodies. (Laughter.) With his old friend, Benjamin Disraeli, he (Sir William Gull) could only say, "Thank God we are not governed by logic." (Laughter.) Mr. McVail had said the Council was responsible for the entire examination, although what it simply had to do was to appoint the necessary examiners. Perhaps when he next spoke he would assert that the Council was responsible for the issues of life and death. He (Sir William Gull) should certainly vote for Mr. Carter's motion.

Dr. LEISHMAN heartily supported Mr. Macnamara's amendment, because he was distinctly of opinion that the examiners to be appointed should be responsible to the Council for every detail of the examination.

Dr. HAUGHTON could not vote for the motion, because he was convinced that the Council had power to appoint examiners in midwifery and medicine as well as in surgery.

Dr. HERON WATSON suggested that, in order to avoid further delay, the Council should itself go into committee on the subject. The Apothecaries' Society had asked that certain gentlemen should be appointed, and had thereby exceeded their powers, inasmuch as the Act enabled them only to apply for examiners, and not to nominate them. He understood that the examination fee was six guineas, and he should like to know whether it was sought to have the Society rehabilitated in order to cheapen the process of obtaining a licence in medicine, surgery, and midwifery. The varying prices of diplomas were a melancholy fact, and he thought it would be desirable that the Council should insist upon a levelling up, not only as regarded the fees, but also as to the times of examinations. In conclusion, he said that he should vote for the amendment.

Further debate was at this point discontinued, and the Council adjourned for a short time, having unanimously agreed in the meanwhile, on the motion of Dr. Quain, seconded by Mr. Macnamara, to the adoption of the report of the Pharmacopœia Committee. When the Council reassembled,

Mr. CARTER said he should like to be permitted to withdraw his motion, and the Council having agreed to allow him to do so, Mr. Macnamara's amendment became the substantive motion, but this in turn was withdrawn in favour of Mr. McVail's proposal, to the effect "That a committee be appointed to consider, with such legal assistance as they may require, the number of assistant examiners that should be appointed to the Society of Apothecaries of London, the subjects in which they should respectively examine, and the powers and duties which they may consider the Council should by order prescribe, also as to the remuneration of the assistant examiners, and to report to the Council at its present session."

Sir W. FOSTER then moved, as an amendment, "That pending a full consideration of the best mode of carrying out the resolution of the Council to appoint assistant examiners to the Society of Apothecaries under the provisions of the Medical Act (1886), and subject to further resolutions of the Council under Section 5 of the Act, the Council hereby appoint Messrs. Makins, Walsham, and Andrew Clark as assistant examiners for the Council for one year from July, 1887." He said the matter was a very serious one, but he could not see how during the present session the Council could obtain all the requisite information for its guidance. The Council might be compelled to act in a way not contemplated by the framers of the Act, but before going to that extreme full time was needed for deliberation; whilst it was not unlikely that counsel's opinion would have to be taken and arrangements made to confer with the leading officials of the Privy Council. The gentlemen named in his resolution would be appointed, not at the dictation of the Society, but because they were members of the profession, and had been introduced to the Council as fit and proper persons to conduct the examination. To add these examiners to those on the Society would not in any way prejudge the question, and during the interval legal advice could be obtained as to future procedure.

Dr. QUAIN seconded the amendment on the ground that it would be impossible to go into and present a satisfactory report upon the subject during the current session. To his mind, however, there could not be any difference of opinion as to whether the Council could appoint examiners in all subjects or in only one, and he thought they ought to confine themselves simply to what was asked for—viz., examiners in surgery.

Dr. LEISHMAN suggested the appointment of an examiner in surgery, medicine, and midwifery respectively, instead of three in surgery.

Sir W. FOSTER thought that to do so would prejudge the question, which would not result if his amendment was adopted in its present form, because the gentlemen mentioned therein were simply styled "assistant examiners."

Dr. A. SMITH looked upon the amendment as a mere substitute for Mr. Carter's motion, and he objected to this attempt to obtain by a side wind what had been refused when put in another form. The Council ought to possess complete control of the examinations, but if they were to accept Sir W. Foster's amendment they would find themselves shorn of their power to do so.

Dr. BRUCE was in favour of the amendment. The Society's examination hitherto had been accepted as sufficient, and the body ought not be unnecessarily interfered with; but it was doubtless desirable that its standard of efficiency should be raised, and, having regard to the words of the Act, he thought it was the duty of the Council to supplement the existing board by appointing assistant examiners in surgery, medicine, and midwifery. It was only proposed to continue the present arrangement for a year. Next year the Council could consider the whole question, and see that the examinations were what they should be.

Sir WM. TURNER thought that Mr. McVail's motion, perhaps with some little modification, was the best that could be adopted. He did not at present see his way to a true interpretation of the words of the Act, and an authoritative opinion was wanted upon the subject. For that purpose it would be best to refer the matter to a committee. He could not, however, think that it was the intention of the Legislature to establish anything like a State examination. Sir Walter Foster's amendment appeared to him to be a proposal to shirk the difficulty, at least for a year, and to sanction the existence of the examinations of the Society of Apothecaries precisely as they had been conducted.

Dr. HAUGHTON referred to the answers given by the Attorney-General, the Solicitor-General, and Mr. Muir Mackenzie on the points submitted to them. A question had been raised as to whether, if a university were to give a degree in medicine, another in surgery, and another in midwifery, the holder of them would be entitled to registration. He understood the answer to be in the affirmative: "Such evidence can be either by diploma, or diplomas granted by the combined body, or by a certificate, or in any other manner that the General Council or Branch Council may consider satisfactory." He presumed that the conjoined bodies or universities might send up diplomas or qualifications without a special certificate. The Apothecaries' Company was already qualified to give a diploma in medicine and midwifery; and the Council, in supplying an additional examination in surgery, had placed the Society in the position of a conjoint body, and had not given it the right to conduct a State examination. By the addition of surgery the Society would be able to give three diplomas, the production of which would entitle the holder to be placed upon the Register. He supported Mr. McVail's motion. The authorities in Dublin considered that it was absolutely in the power of the Council to give directions to the Registrar in the sense he had indicated.

Mr. SIMON said the Council would be going beyond its powers in agreeing to the amendment. The Act gave the Council power to appoint additional examiners "from time to time," and the present motion was to appoint them for a limited time only. According to his reading of the Act the duty of the Council was simply to supply a specific deficiency; it had not a general commission to improve the examinations of the licensing bodies except by means of inspectors, and by reporting when necessary to the Privy Council. The two things ought not to be confounded. He supported the amendment of Sir Walter Foster, which simply accepted provisionally the arrangements in force at the Society of Apothecaries for a limited period, and subject to any further resolutions of the Council under Section 5. If there were a reference at all, it ought to be to the Executive Committee.

Dr. DUNCAN supported Sir W. Foster's amendment, but expressed his dissent from most of the speeches that had been delivered in its favour.

Dr. GLOVER said the Medical Council had an awkward habit of postponing its duties. He had himself found in

Digitized by Google

private life that however difficult a thing might be to-day, it was still more difficult if put off till to-morrow. That rule applied, he thought, to the present position of the Council. They owed it to themselves and to the Society to settle the business during the present session. If the matter were postponed, the Society of Apothecaries would be living for twelve months in a state of suspended animation. It was due to the Society that the Council should complete its equipment as rapidly as possible.

Mr. CARTER said that on behalf of the Society of Apothecaries he cordially supported the motion of Sir Walter Foster. As to the weekly meetings of examinations, the fees paid, and other matters of the kind, they were all settled by Act of Parliament; but the Society intended, as soon as it was relieved from its present state of suspense, to apply for an Amendment Act so as to bring the arrangements more in harmony with present-day requirements. There was no intention on the part of the Society to dictate to the Council. If the Amendment were adopted, there would be ample time to consider the many difficult problems requiring solution, and the ordinary work of the Society would still be conducted in an uninterrupted manner.

Dr. STRUTHERS said that, as he had foreseen, the letting out of the waters had already begun. Sir Walter Foster's amendment was a very clever and ingenious way of getting out of the difficulty; but it certainly prejudged the question.

Sir W. TURNER said it was the duty of the examiners to take cognisance of medicine, surgery, and midwifery, and he wanted no lawyer's opinion upon the subject. Indeed, the Council had no choice in the matter.

Dr. KIDD called attention to a statement in the report of the visitors that the examiners of the Society of Apothecaries were not bound to examine in any special subject; but undertook the examinations for periods of five weeks. It was, however, generally recognised at the present time that all examinations should be conducted by experts.

Mr. CARTER said that on the recommendation of the Council the system had been altered.

Mr. MCVAIL said that if Sir Walter Foster's amendment were adopted, the Society of Apothecaries in its present state would be perpetuated for another year, and he maintained that the Council had no power to bring about that result. One consequence of it would be that when there was the least difference on the part of any combining body there would be a split up of the whole thing, and more examining bodies would have to be appointed.

On a show of hands being taken for the amendment, 12 voted for it and 14 against. For: Mr. Wheelhouse, Dr. Fergus, Mr. Teale, Dr. Haughton, Mr. Collins, Sir W. Foster, Dr. Pyle, Dr. Quain, Mr. Simon, Dr. Bruce, Mr. Carter, and Dr. Moore. Against: Dr. Struthers, Sir Dyce Duckworth, Sir W. Turner, Dr. Banks, Dr. Pettigrew, Dr. A. Smith, Dr. Leishman, Dr. Tuke, Dr. Heron Watson, Dr. Kidd, Mr. McVail, Dr. Glover, Mr. Macnamara, and Dr. Chambers.

Some discussion took place on a motion for the adjournment of the debate. On a show of hands the motion was negatived, but on the names being taken and the numbers counted it was declared to be carried by a majority of one.

SATURDAY, MAY 14TH.

MR. MARSHALL, PRESIDENT, IN THE CHAIR.

A communication was received, and ordered to be entered on the Minutes, from the London School of Medicine for Women, petitioning the Council that, in the event of their appointing examiners in surgery for the Society of Apothecaries of London, they would urge upon the Society the duty of recognising the School and admitting its students to the benefits of the Society's examinations and licence.

Sir WILLIAM GULL gave notice that he would call attention to the subject at a future sitting of the Council.

The following *ad interim* report was received from the Income and Expenditure Committee:—

The Committee appointed to consider the past income and expenditure of the Council, and to report to the Council whether any, and if so what, diminution can be made in the future expenditure of the Council, and also whether, and in what manner, its income may be increased, make the following *ad interim* report.

The average annual income of the General Council and of the three Branch Councils for the past five years has been as follows:—

General Council ...	£5679 5 0	Scotch Br. Council ...	£1933 0 2
English Br. Council ...	4730 14 3	Irish Branch Council	1276 4 0

The average yearly total income (£8877 14s. 6d.) of all the Councils for the past five years—as set forth in Table A—includes, however, exceptional receipts from the new edition of the Pharmacopœia. If the average yearly amount (£881 6s. 4d.) which has resulted from the sale of Pharmacopœias during the past five years be deducted, the average annual income of the General and three Branch Councils amounts altogether to £7996 8s. 2d.—that is to say, in round numbers to about £8000. The committee are unanimously of opinion that there are at present no available means of increasing the income of the Council. It has been suggested that a registration fee might be charged for medical students, but the committee are unanimously of opinion that this cannot be recommended.

The expenditure of the General Council and of the three Branch Councils during the past five years is set forth in Table B, which shows the annual averages during that period to have been as follows:—

General Council ...	£5679 5 0	Scotch Br. Council ...	£444 9 1
English Br. Council ...	875 19 10	Irish Branch Council	487 2 7

The expenses and balances of receipts of the three Branch Councils for the past five years are set forth separately, in detail, in Table C. It results, therefore, that the annual average of the total income for the past five years of the General Council and of the three Branch Councils—excluding, for purposes of comparison, the exceptional receipts that have, as before stated, arisen in connexion with the Pharmacopœia—amounts to £7996 8s. 6d.; and that the expenditure has been £6789 14s. 8d., thus leaving a yearly balance in favour of income of £1206 13s. 6d. These yearly balances have, from time to time, been invested in Consols by the Branch Councils, thus giving now a total of investments of £38,169 17s. This expenditure will, at the present rate of payment, be increased by the enlargement of the Council: and the increase will probably be to the extent of nearly one-fourth, the proportion in which the number of Council members will be ultimately increased. It becomes thus manifest that if the income and expenditure of the enlarged Council are to be brought into satisfactory relation, and if there are no means available for increasing the income, it will be necessary to reduce the expenditure. Among the items of expenditure, those which are attendant upon the meetings of the General Council have received the serious consideration of the committee, and the committee are of opinion that this expenditure should be reduced. But they defer making any proposal as to the method of effecting such reduction until the report by the Procedure Committee shall have been considered by the Council.

May 12th, 1887. G. M. HUMPHRY, Chairman.

An opinion was read from the Attorney-General, the Solicitor-General, and Mr. Muir Mackenzie, in answer to the following questions:—

(*a*) Whether the sanction of the Council is necessary in order to enable the medical bodies mentioned in the Act of 1886 to combine for the purposes of the examinations therein mentioned; or whether such bodies can combine without the sanction of or reference to the Council. (*b*) If counsel are of opinion that the medical bodies can legally combine without the sanction of the Medical Council, whether the General Council or Branch Councils, through their registrars, can or should require evidence, either from the diploma or diplomas granted by such combined bodies, or from a certificate to accompany such diploma or diplomas, that the person receiving it or them has passed the necessary qualifying examination, and that the examination has been conducted by bodies who have legally combined under the Act of 1886.

The opinion was as follows:—

(*a*) In our opinion, the sanction of the General Council is not necessary in order to enable the medical bodies mentioned in the Medical Act, 1886, to combine for the purposes of the examinations therein mentioned, and such bodies can combine without the sanction of or reference to the General Council. (*b*) In our opinion, the General Council or the Branch Council through their registrars can and should be satisfied that each person who presents himself for registration has passed the necessary qualifying examination, and that the examination has been conducted by bodies who have entered into a valid combination, under the Act of 1886, s. 3. Such evidence can be afforded either by the diploma or diplomas granted by the combined bodies, or by a certificate, or in any other manner that the General Council or Branch Council may consider satisfactory.

R. E. WEBSTER.
EDWARD CLARKE.
The Temple, March 30th, 1887. M. MUIR MACKENZIE.

A letter was read from the Lord President of the Privy Council, together with a copy of an Order in Council of the 25th March last, declaring that Part 2 of the Medical Act of 1886 shall apply to the colony of New Zealand.

Certain regulations were received for the diploma in Public Health of the University of Aberdeen.

A communication was received from the Science and Art Department with reference to the International Conference on Hygiene to be held next September in Vienna, and stating that, should the Medical Council wish to nominate a delegate, the Secretary of State for Foreign Affairs had expressed his readiness to furnish his name to the Austro-Hungarian Government.

The adjourned debate of Mr. McVail's motion with reference to the Society of Apothecaries was resumed.

Mr. SIMON said that the motion as to the appointment of assistant examiners referred to "the subject in which they should respectively examine." He suggested that the words should read "the subjects in which they should respectively or collectively examine." The words proposed by Mr. McVail appeared to prejudge the whole point at issue.

Mr. MCVAIL accepted the proposed modification.

Dr. HAUGHTON moved as an amendment "to omit the words 'a committee be appointed,' and to substitute for them 'the executive committee be requested.'" The Council had passed a resolution affirming the principle that it would supplement the Society of Apothecaries' examination by the appointment of examiners in surgery only. There

Digitized by Google

was no power to thrust on the Society an examiner in medicine and midwifery, and if the Council did so he believed that the Society might resist it in a court of law. If the College of Surgeons were under consideration the Council would have to give them supplemental examiners in medicine; and in the same way it had to give the Society of Apothecaries examiners in surgery. The principle of Mr. Carter's resolution had been adopted by a large majority, but the Council appeared to be hopelessly divided on the question of how to carry it out. There was the same confusion among the members of the Council as there would be among the judges of the Court of Queen's Bench if they tried to treat a case of fever. He did not think that any committee would be able to settle the question during the present session. Under all the circumstances, he thought the best course was to refer the question to the Executive Committee, who were accustomed to deal with such matters. He believed that it was beyond the power of the Council to appoint examiners in medicine or midwifery for the Society of Apothecaries, and if it had the power it would be unwise to exercise it.

Mr. MCVAIL said that the Executive Committee was a small body, and he believed that the members of it were all of one way of thinking. He therefore objected to the question being remitted to that committee; a larger committee should be appointed on such an important question.

Dr. HAUGHTON said he did not know who constituted the Executive Committee, or what views they entertained.

Mr. MCVAIL said he had no objection to include in the committee that would be appointed under his motion all the members of the Executive Committee.

Dr. HAUGHTON said that under those circumstances he would withdraw his amendment.

Dr. H. WATSON said he did not approve of the matter being referred to the Executive Committee, and did not desire that it should be relegated to another session. If the Council did nothing more than appoint surgical examiners, he did not think it would incur the opprobrium of setting up a gigantic examining body; but he strongly held the view that the Society of Apothecaries should be aided by the Council by the appointment of such assistant examiners as the Council thought fit, in order to make it an efficient board.

Dr. QUAIN moved an amendment to the effect that it was unnecessary to refer the matter to any committee, and that the Council proceed to comply with the request of the Society of Apothecaries. He said he hoped the Council would not commit itself to so false a step. There was not a shadow of pretence for saying that the Council had any other duty than that of appointing examiners in surgery for the Society of Apothecaries. The Act of Parliament stated that examiners should be appointed to the bodies concerned "on their application," and the Society had only applied for examiners in surgery.

Mr. B. CARTER seconded the amendment. He said he had no sympathy with the imaginary difficulties that had been raised by many speakers. The intention of the Act was clear, although its language was in many respects defective and involved. The great peculiarity of the case of the Society of Apothecaries was that the inability was not a real but only a technical one. They had the examiners, although they had not the statutory right, and he asked the Council to recognise the existing position of things. The direct question which they had to determine had been lost sight of. His willingness to consent to a reference to the Executive Committee arose from the fact that that committee consisted of gentlemen accustomed to transact business expeditiously, and he knew that when they went to the law officers of the Crown the contentions raised about the responsibilities the Council was going to assume would be scattered to the winds. He could not, however, agree to a reference to a committee *ad hoc*.

Mr. SIMON said that if the proposed committee were to take legal advice of a quality sufficient to satisfy every scruple of every member of the Council, the proceedings must occupy considerable time. The opinions of solicitors and attorney-generals could not be obtained in a day. There might be a difficulty in the selection of the members of the committee, and would it not be better that the Council settled the matter itself? He had no right to go back on the amendment which was rejected yesterday afternoon, but it was rejected by an accident, after the Standing Orders had been suspended, and when one or two of those who were in favour of it were absent. Would not the simplest way of dealing with the matter be to invite Mr. Muir Mackenzie to attend and answer any questions that might be put to him? Some of them dissented from the principle of what they were doing, but if his suggestion were adopted they would be able to take part in the consultation, while great embarrassment would arise in the appointment of a committee. If they did it in full Council, with the assistance of the legal adviser, he thought they could not go very wrong, and much time would be saved.

Sir W. TURNER said, although Mr. McVail's motion to a large extent met with his approval, he thought that under the circumstances in which they were placed Mr. Simon's suggestion would better meet the most important of their difficulties. He would ask Dr. Quain to withdraw his amendment and allow Mr. Simon to substitute for it one expressing in terms the suggestion that he had made.

Dr. HERON WATSON considered that the solution of the position suggested by Mr. Simon was really the only possible one. He could not, however, coincide with the proposal to have legal advice. So far as he had seen, the advice which they had of late received from the solicitor and counsel had rather tended to darken judgment than to clear it up.

Dr. QUAIN consented to Sir Wm. Turner's suggestion.

Sir WM. GULL could not see why the Council should not proceed to do their duty. He could see his way clear enough. He had no doubt that it was his duty to help to appoint assistant examiners, and in his opinion it should be done at once. Metaphysics and logic and theory had been indulged in; but the Council had its work to do, and any plain Englishman could in five minutes do all the work which had taken three days.

Dr. DUNCAN said he did not quite agree with the views expressed by any of the previous speakers. The Council had settled that they were to proceed with the appointment of the assistant examiners to the Apothecaries' Society, and the point that was not decided would not be settled by Mr. M'Vail's resolution or by Dr. Quain's amendment. Underlying all other matters was the question whether the Council were to take charge of the entire examination by the Apothecaries, or whether they were merely to do what the Act prescribed--namely, to appoint assistant examiners. When that was settled the whole question would proceed easily. Was the Apothecaries' Society in future to be a mere creature of the Council, or was it to be, as it had hitherto been, a body of independent examiners, with assistants sent to them by the Council? Mr. McVail and his supporters hoped to establish the principle that the Apothecaries' Society should in future exist, not in reality, but merely virtually; that as an examining board it should be a mere creature of the Council, and that the Council itself should examine in all branches through the Apothecaries' Society. No one could read the Medical Act and suppose that that was the intention of the Legislature. The word "assistant" was enough to settle the whole matter. He would suggest another amendment, which would not require legal advice: "That the assistant examiners about to be appointed are to be such as are required by the Apothecaries' Society, with a view to the completion of the board of examiners under the Act of 1886."

Dr. HERON WATSON.--That does not clear up the difficulty.

Mr. MACNAMARA thought the difficulty would be solved if the legal adviser attended at two o'clock next Tuesday.

Dr. Quain's amendment was thereupon withdrawn in favour of the following, moved by Mr. Simon, and seconded by Dr. Quain: "That the Council will on Tuesday next, at two o'clock, consider in committee the steps by which to give effect to its resolution of May 13th for the appointment of assistant examiners to the Society of Apothecaries, and that a request be made to Mr. Muir Mackenzie and Mr. Farrer for their attendance on that occasion."

Mr. M'VAIL said that after discussing the subject for nearly a week the Council had now got into a position of grave legal difficulty, and the time was very short before June 30th. In the interest of the Apothecaries' Society the matter should be quickly settled. It was therefore advisable to refer it to a committee to prepare for the discussion next Tuesday, and to lay before the legal advisers the difficulties which the Council felt, and which they were incapable of settling. Evidently Mr. Simon meant to oppose to the death the views of some members of the Council. By motion after motion obstructing the inquiry he showed that he was determined that his view of the duties of the Council should be carried.

Digitized by Google

Mr. SIMON said such personal imputations were contrary to the practice of the Council. He could not more clearly show that he was not pressing any personal view on the Council than by asking that their legal advisers might attend.

Mr. MCVAIL said he did not impute any personal motive to Mr. Simon, who was simply acting according to what he considered his duty, but he opposed the inquiry by amendment after amendment, and was conducting his opposition with a degree of persistency that was unusual in the Council. The opinion of the committee might come before a committee of the whole House, and it was extremely desirable that then the legal advisers should be present. If the Council declined to proceed with the matter until Tuesday, they would either have to sit an absurdly long time, or would have to be called together again before June 30th.

Dr. BANKS heartily supported Mr. Simon's motion, as he considered it the only practicable way of getting out of the difficulty. If the discussion were continued much longer, he thought the power ought to be conferred upon the President, which was exercised in another place, to put a stop to it.

Dr. KIDD thought that the different views might be harmonised. There were certain duties laid down by the statute which Mr. Simon's amendment did not cover. The Council had to fix the time of the examinations, to decide how the standard of education and examination was to be maintained, and to consider the powers and duties to be conferred on them, as well as the remuneration. It would probably meet the views of the Council if the motion ran: "That a committee be appointed to consider, with such legal assistance as they may require, the number of assistant examiners that should be appointed to the Society of Apothecaries of London, the subjects in which they should respectively examine, and the powers and duties which they may consider the Council should by order prescribe, and also as to the remuneration of the assistant examiners, and to report on Tuesday at two o'clock, when the legal adviser should be requested to attend."

Dr. BRUCE said there appeared to be an attempt to put the cart before the horse. The first thing the Council had to do was to make up its own mind. Referring the matter to a committee was a silly proceeding; it was passing away their responsibility to a committee. The right and proper thing to do was to first settle the legal question, and then they might appoint a committee.

Dr. GLOVER wished to ask the older members of the Council if they ever remembered a question of such magnitude being settled without the previous appointment of a Committee to draw up a careful statement, and then to come to the Council with the best basis they could arrive at. With regard to the legal construction, he thought it would be shown that their duty would be limited to the appointment of surgical examiners, but the question would come out in the report of the committee, who would certainly be very much fortified by having a lawyer present at their meeting. He would appeal to Mr. Carter, after the friendly vote of Thursday and the disposition shown by the majority of the Council to treat the Apothecaries with great faithfulness and justice, to give the members credit for wishing as well to the Society as he did himself.

Mr. SIMON said that, to the best of his recollection, there had never been a case of this kind before. There were groups in the Council holding fundamentally different opinions on a point of law, and a settlement could not be arrived at by a Committee. After hearing Mr. Muir Mackenzie's opinion each member of the Council would be able to satisfy himself as to the construction of the law and to put questions to counsel.

Sir W. TURNER said that the presentation of the amendment by Mr. Simon had put the question in a very different aspect, because it now appeared that all parties in the Council were of opinion that additional advice was needed before the matter was dealt with. He did not consider that a special committee was needed. Every member of the Council had the points in dispute clearly in his mind, so that it seemed to him that Mr. Simon's suggestion was the more practical. If it were agreed to, then the Council, before it parted on Tuesday afternoon, would be able to do what they were advised to do.

Dr. STRUTHERS could not agree with Sir W. Turner. He thought the motion and amendment might be worked in together. Besides the point of law, there were a number of other matters to place before counsel, and if that were done, then on Tuesday they might come to a decision.

Mr. MCVAIL said he was willing to adopt Dr. Kidd's amendment if Mr. Simon would do the same.

Mr. SIMON would not consent to this course.

Dr. QUAIN said, in answer to Dr. Glover, that the usual way had been for the President to communicate to the solicitor the question under discussion, and, no doubt, that course would be followed in the present case.

Mr. Simon's amendment was then voted upon, and carried by 21 to 5.

On its being put as a substantive motion,

Dr. KIDD moved the amendment which he had previously referred to.

Dr. PETTIGREW seconded the amendment, but it was lost by 18 to 8.

The PRESIDENT said that he regarded it as his duty, in the present crisis, to prepare a case and a series of questions to be submitted to the lawyers before Tuesday. He congratulated the Council on the failure to carry Mr. McVail's motion, because it had struck him all along that the words "such legal assistance as they may require" involved an exceptional and altogether wrong power. The committee, if appointed, would have been able to go outside the legal advisers of the Council and obtain opinions from Scotland or Ireland.

Mr. MCVAIL.—Certainly.

Mr. SIMON's motion was then agreed to *nem. con.*

The Apothecaries' Hall of Ireland.

Mr. COLLINS moved: "That inasmuch as the King and Queen's College of Physicians and the Royal College of Surgeons in Ireland have declined to comply with the request of the Medical Council of Feb. 16th, 1887, that the Colleges should combine with the Apothecaries' Hall of Ireland for the purpose of holding qualifying examinations in accordance with the provisions of the Medical Act (1886), and the Governor and Court having made application to the Medical Council for the appointment of assistant examiners, the Council do now appoint such examiners accordingly." In doing so he said the Registrar of the College of Physicians had sent him a statement, with the request that he would carefully consider it. He had done so, and he thought there were certain portions of it calculated to produce an erroneous impression upon the members of the Council. The Act of 1791 was "for the more effectually preserving the health of His Majesty's subjects, for erecting an Apothecaries' Hall in the city of Dublin, and regulating the profession of an apothecary throughout the kingdom of Ireland." The members of Parliament who passed it knew very well what the meaning of the word was, but the contention of the College of Physicians of Ireland was that the licence of the Apothecaries' Hall was only a licence in pharmacy. If that had been the intention of the Irish Parliament, the words would have been "for regulating the practice of pharmacy in Ireland." It should be known that the College of Physicians was at that time just as much opposed to the idea that the apothecaries of Ireland should practise medicine as they were at the present time. In one part of their statement it was said that in 1791 there were no apothecaries in Ireland properly so called, but the Act was passed "at the request of the master, wardens, and commonalty of the corporation of apothecaries and other apothecaries of the city of Dublin." Therefore there were apothecaries at that time because the Act was passed at their request. He at once acknowledged that the Hall mixed up trade with profession, and the Irish Parliament and the English Parliament intended that they should do so. There was not a single word in the Act directing the appellant examiners to confine their examinations to materia medica, pharmacy, and chemistry, nor did it preclude them from examinations in the practice of medicine. The legal opinion of Sir Joseph Napier was that no such thing was intended by the Act, and that it would be an anomaly to give the appeal to the College of Physicians without expecting them to examine in the practice of medicine. What made that perfectly certain was this: they had, as a board of examiners, to institute examinations for apprentices, and to give examinations to assistants, and then the final examination for licence to practise as an apothecary. Now an apprentice and an assistant, if three times rejected, had an appeal to the General Council of the Hall, but an apothecary was allowed to appeal to the College of Physicians because they had to examine him to see that he was not unfairly rejected by the examiners of the

Digitized by Google

Hall either in pharmacy or in the practice of medicine. The Act left the Hall perfectly at liberty to examine in every subject from time to time. The Apothecaries' Society of London were obliged to have an examination every week, but there was no such limitation in the Irish Act, which left the Hall at liberty to make changes from time to time as circumstances and the progress of knowledge might require. Dr. Kidd had said that the College of Physicians had not declined to comply with the request of the Hall, but in his opinion an offer based on impossible conditions was the same thing as declining. The condition was that the Hall should take some kind of case to the Queen's Bench at Dublin and have it decided at their own expense, for the satisfaction of the College of Surgeons and the College of Physicians, before they were admitted to the conjoint examinations. He had asked Mr. Purcell whether the College of Surgeons could be satisfied in that way—by bringing a sham friendly case into the Queen's Bench; and the answer was that there was no way of doing it until the Hall had an independent position, or until they joined with the College of Surgeons, and then, if the College of Physicians chose to go to law, the question might be brought into court. The efforts to bring about a Conjoint Scheme in Ireland went on for three or four years—from 1871 to 1875. First, the two universities and the three corporations endeavoured to combine; afterwards, the University of Dublin and the three corporate bodies tried to form a Conjoint Scheme; and, finally, the three corporate bodies alone formed such a scheme, but it came to nothing because the two colleges could not agree upon pecuniary matters. It was said that efficient examiners could not be obtained among the existing directors of the Hall; but of the sixteen examiners, only two held the qualification of the Hall alone, six had double qualifications, and seven had triple qualifications. It had been stated that only one of the examiners was a licentiate of the College of Surgeons in Ireland, but there were four. He himself had kept up his knowledge of medical and pharmaceutical chemistry to the present day, and in reality the examiners were all experts. When the visitors from the Council attended at the examinations, the Hall came off just as well in the reports as any of the other bodies that were visited. Of course some fault was found, but not more than was found with the College of Physicians, and Dr. Gairdner was astonished at the admirable examination in hygiene. The Hall, too, was complimented by the visitors on the examination in midwifery.

Four o'clock having arrived, the debate was adjourned.

MONDAY, MAY 16TH.

MR. JOHN MARSHALL, PRESIDENT, IN THE CHAIR.

On the motion of Mr. WHEELHOUSE, seconded by Dr. STRUTHERS, a communication from the Parliamentary Bills Committee of the British Medical Association, requesting the attention of the Council to the provisions of the Pharmacy Acts Amendment Bill, was received and entered on the Minutes.

The Practical Education Committee, which was appointed (1) to consider the best methods of increasing the practical element in medical education, as by a system of limited pupilage with a registered practitioner, and (2) by insistence on more clinical, therapeutical, and pathological teaching and work in medical schools, now reported that it had had under its consideration the large proportion of rejections at the final examinations of many of the medical authorities, together with other facts which seemed to show a deficiency in the knowledge of practical subjects on the part of candidates. It was of opinion that such deficiency was, primarily at least, the concern of the medical authorities, and that they were best able to make such changes in their curriculum and examinations as would effect the improvements to be desired in medical teaching. On the question of pupilage, the committee was of opinion that, in some way, the advantage to be derived from personal instruction was of too great value to be altogether sacrificed, and suggested that a period of not less than six months should be spent in personal pupilage—not necessarily six consecutive months, but six in all; that personal pupilage should imply not only the study of the routine of medical life and its accessories, but also, at some period of its duration, the responsible charge of patients under efficient supervision. They also recommended that the six months should be taken during the long vacation, and after the examinations in anatomy and physiology had been passed. On the subject of school and hospital study, the committee drew attention to a resolution which had already been before it, and which stood recorded in its Minutes—viz.:

"That it be a recommendation to the licensing bodies that in admitting candidates to professional examinations care be taken that attendance on courses of study prescribed for any second professional examination shall qualify only if made *after* the first examination has been passed, and generally that attendance prescribed for any subsequent examination must be made after passing the immediately preceding examination."

In conclusion, the committee offered the following suggestions:—

1. That the Council, with a view to increasing the practical elements in medical education, should circulate a recommendation to the examining bodies to make the practical part of examination in medicine, surgery, and midwifery more extended and more searching than it has hitherto been, so that it may form a surer guarantee of the possession by the candidate of the required skill for the safe practice of the above-named arts. 2. That it be a recommendation to the examining bodies, in their clinical examinations, to give more prominence to the recognition and treatment of common diseases; and to facilitate the extension and searching power of these examinations, the "final" or qualifying examination should be divided into two parts, of which the ultimate should consist mainly of clinical work and the personal application of diagnosis, prognosis, and treatment to set cases, leaving to the penultimate the testing of the knowledge possessed by the candidate of the other subjects contained in the curriculum of school work. 3. That it be also recommended that there should be an interval of at least twelve months between the two parts of the final examination, and that this interval should be passed in such occupations as will involve the charge of patients under the supervision of competent persons recognised by the authorities of the school at which the candidate has been educated, which authorities should be responsible for the genuineness of the evidence afforded of the candidate's diligence and care of such number of cases of medicine, surgery, and midwifery as the examining body shall deem expedient.

On the motion of Mr. WHEELHOUSE, seconded by Dr. STRUTHERS, the report was received and entered on the Minutes.

The report of the Procedure Committee, appointed "to consider under what rules of meeting and procedure, and with what appointment and authorisation of standing committees and subcommittees, the Council may best provide for the regular, effective, and economical discharge of its statutory duties, the committee to report to the Council at its next meeting, and to propose for consideration of the Council the draft of any new Standing Orders which it may deem desirable," was received and entered on the Minutes.

Visitation and Inspection of Examinations.

The Council having referred to the Executive Committee the arrangements to be made in regard to inspectors of examinations, the committee now presented an interim report stating that it had passed the following resolutions:—

(*a*) "That it be an instruction to the inspectors on the present occasion that they give special attention to the quality of the practical examinations, and to the sufficiency of the means and appliances which are in use in them for testing the qualifications of candidates." (*b*) "That each inspector, within the period of twelve months from the date of his commission, inspect, as regards his subject matter, the qualifying examinations of all the licensing bodies, and report thereon to the Council."

Adjourned debate on the application of the Apothecaries' Hall of Ireland.

Mr. COLLINS, in continuing his address in support of his motion, proceeded to deal with the contention of the King and Queen's College of Physicians that the Apothecaries' Hall had no legal status beyond the appointment of pharmacists, referred to various Acts of Parliament passed during the last century, in which apothecaries were appointed in the same category as physicians and surgeons to attend the county gaols. The present Apothecaries' Act was passed by the Irish Legislature in 1791, and contained provisions for the education and examination of apprentices, assistants and licentiate apothecaries. To show the kind of education given, he stated that when he passed the Hall in 1826 he was examined in Greek, Latin, and English, the subjects being the first two books of Sallust, the first six books of the Æneid, and the first two books of Homer. Having passed that examination, he was bound to an apothecary, and after a certain time, wishing to become an assistant, had to undergo an examination in materia medica, chemistry, and pharmacy. Acts of Parliament passed in 1817 and 1823 stated that persons might be admitted into hospitals on the certificate of a certified apothecary or surgeon, and defined the term "medical officer," as meaning a physician, surgeon, or apothecary. By an Act of 1841 the certificates of two "apothecaries" were made equally valid with those of two physicians or surgeons with reference to the reception or detention of any person in a lunatic asylum; and by a

Digitized by Google

second Act it was provided that no ship carrying a certain number of passengers was to proceed on a voyage without having on board a "physician, surgeon, or apothecary." He contended that the Apothecaries' Hall had fulfilled its duties, and had given its licentiates such an education and examination as would fit them, in some respects at all events, for the important positions they had to occupy, and for the practice of medicine as well as pharmacy. He referred to the hostility which the Hall had met with from the College of Physicians, although he was not aware that it had done anything to provoke it. Since 1791 it had licensed about 4000 practitioners and was still in a state of vitality, yet the Medical Act of 1886 placed all the various bodies in a new position. The Apothecaries' Hall must come up to that position and undertake the responsibilities, and his colleagues were fully prepared to do so. It was a mistake to say that there were only 387 licentiates of the Hall, for at the present time there were between 900 and 1000 in Ireland. If there were only 800, that would be one-third of the medical practitioners of Ireland, and till 1851 the majority of the practitioners in Ireland were licentiates of the Apothecaries' Hall. They were recognised as medical practitioners not only by the old Acts, but also by the Act of 1858 and the Act of 1886. He relied on the justice of Englishmen, Scotchmen, and Irishmen to aid the Apothecaries' Hall.

Dr. BRUCE seconded the motion. The Council, he said, had recognised the English Society, and in all fairness they ought to recognise the Irish Apothecaries' Hall.

Mr. TEALE felt that the Council had no other course open to it than to accede to Mr. Collins' motion. As they had decided in favour of the Apothecaries' Society of London, he did not see how they could refuse the request of the Apothecaries' Hall of Ireland. By the Act of 1858 they had been obliged to register the licentiates of the Hall, and that arrangement was not disturbed by the Act of 1886.

Dr. STRUTHERS had no objection to offer to admitting the Dublin Society of Apothecaries to the same privileges as the London Society. Still, it must be remembered that the Council were threatened with an action at law by the Dublin College of Physicians. Opinions had been obtained in Ireland in favour of both sides of the question. The College of Physicians contended that the Apothecaries' Hall had no legal power to grant a licence to practise medicine; and the opinion of counsel was "that the Apothecaries' Hall has no power to grant a diploma or licence to practise medicine." On the other hand, Mr. Purcell, Q.C., said: "I am clearly of opinion that the General Medical Council has no power to exclude the holders of such diploma from registration." He would therefore move—"That, inasmuch as a legal question has been raised by the King and Queen's College of Physicians in Ireland as to the right of the Apothecaries' Hall of Ireland to have assistant examiners appointed for them, to enable them to separately hold qualifying examinations within the meaning of the Medical Act (1886), or to enter into a combination with the Royal College of Surgeons of Ireland for that purpose, the General Medical Council decline to appoint assistant examiners for the Apothecaries' Hall unless directed to do so by the Privy Council."

Dr. DUNCAN inquired whether the licentiates of the Society of Apothecaries were refused admittance to the army, the navy, or the Poor-law boards of Ireland.

Mr. COLLINS said they were not. The licences were recognised as a qualification in medicine.

Dr. A. SMITH said that the mere licence of the Society of Apothecaries was not held to be sufficient.

Mr. COLLINS said it of course required a surgical qualification, just as did the licence of the College of Physicians. Both were in the same position.

Dr. KIDD seconded the amendment. The best solution of the question would have been to admit the Society of Apothecaries into the combination, but the question had now entered on a new phase. The College of Physicians had threatened to bring the Council before a court of law if it granted assistant examiners or registered men qualified by the College of Surgeons and the Society of Apothecaries. It was necessary, therefore, to obtain a legal decision on the subject, and that could be done by an appeal to the Privy Council. There was really no analogy between the English and the Irish Societies. The Society of Apothecaries were distinctly directed by the Act to examine in medicine, but no such direction was given to the Apothecaries' Hall of Ireland, the preamble of whose Act distinctly defined their duties as compounders of medicine. The question now was whether the Hall came within the definitions of the Act of 1886. In the opinion of Lord O'Hagan and Mr. Justice Lawson the Apothecaries' Company were not entitled to grant a diploma in medicine, and if so they could not combine with a surgical corporation. It was necessary for them to prove their title, and the amendment afforded them the opportunity of doing so by an appeal to the Privy Council. The College of Surgeons had expressed their willingness to combine if the Apothecaries' Hall had the power to enter into a combination, and if the Privy Council decided that they had that power the Medical Council would be relieved from the difficulty as to the question of examiners. The point in dispute was a legal one, and ought to be decided by a court of law.

Mr. SIMON said that the Privy Council, in the sense of Dr. Struthers's proposal, was not a court of law, but a branch of the executive government. The Act of 1858 enacted that a person holding the licence of the Apothecaries' Hall was a qualified practitioner. The Council could not legally refuse the application of the Hall.

Dr. LEISHMAN thought it would be beneath the dignity of the Council to be influenced by the threat of the King and Queen's College of Physicians. He frankly owned that he considered it a mistake that the Act of last year did not extinguish the London Society of Apothecaries, and the same observation would apply with still greater emphasis to the Irish Apothecaries' Hall. There could not, however, be any doubt that the Apothecaries' Hall was a medical corporation, and the Council therefore had no right to refuse their request, particularly after the decision that had been come to with regard to the London Society of Apothecaries.

Mr. MCVAIL said it was beyond dispute that the Act of 1858 made the licentiates of the Dublin Society of Apothecaries medical practitioners. The Society was therefore a medical corporation, and he could not see any ground for doubting what was the duty of the Council in this case.

Dr. BANKS could not vote for giving examiners to the Apothecaries' Hall until the legal question was decided in their favour.

On the motion of Mr. MACNAMARA the debate was adjourned.

TUESDAY, MAY 17TH.

MR. JOHN MARSHALL, PRESIDENT, IN THE CHAIR.

The Council at once resolved itself into committee, and strangers were requested to withdraw.

On the readmission of the public,

Mr. MACNAMARA resumed the debate on the request of the Apothecaries' Hall of Ireland. The case, he said, was not on all fours with that of the English Apothecaries' Society. That Society's Act clearly laid it down that they should examine in medicine, but no such words were to be found in the Acts relating to the Irish Hall. That Hall simply had to examine as to the knowledge of the candidates of the art and mystery of an apothecary. Neither was the case on all fours with the decision come to by the Council in 1863. At that time the Council's decision was final, and there was no appeal; but now there was an appeal. The Council was not only a Council of Education, but was also a Council of Registration, and they were now placed in the position of having to say whether they would or would not set up a body capable of conferring registrable qualifications. At present there were in Dublin two universities—one requiring a complete course of arts, and the other requiring a most satisfactory general education. There were also the Royal Colleges of Physicians and Surgeons, who were prepared to qualify for the Medical Register. The Council was now asked to set up a fourth body in that city. He knew that it would be most destructive to education in Ireland to give the Apothecaries' Hall the power of granting the qualification in medicine. It was not a question of corporate jealousy or a battle of the shops, but the opinion of the profession in Ireland had been deliberately pronounced upon the subject. In 1881 the Irish Medical Association, which included all ranks of the profession, stated before the Medical Acts Commission that the Apothecaries' Hall of Ireland could not be considered anything more than a body for the licensing of pharmaceutists, and that it had no more claim than the Pharmaceutical Society to be represented at the General Medical Council. It was a trading company, and was now so diminished in importance

Digitized by Google

as not to be entitled to the privilege asked for it. Mr. Collins had said that in several claims for joint examination the Apothecaries' Society was included, but that was antecedent to the year 1879, from which date onwards the Colleges had steadily refused to have anything to do with the Apothecaries' Society. It might be true that the public services recognised the qualifications of the Apothecaries' Hall, but they also recognised non-registrable qualifications such as the licence of the Coombe Lying-in Hospital and the Rotundo, and those hospitals might as well call upon the Council to recognise and register their qualifications in midwifery as the Apothecaries' Hall might call upon them to register its qualification in medicine. Mr. Collins had argued that the licentiates of the Apothecaries' Hall were of great value as general practitioners because they were enabled to supply medicine to their patients; but the licentiates of the College of Physicians were not interdicted from supplying medicine, though they were from keeping an open shop for the sale of medicines. The pharmaceutical chemists had entirely taken the place of the apothecaries in Ireland. The Council, before conferring the powers sought for, should see that there was an urgent necessity for doing so, especially when they bore in mind that their decision was not the final one. For these reasons he supported Dr. Struthers' amendment.

Dr. QUAIN said that, inasmuch as Parliament had recognised the Apothecaries' Hall as one of the examining bodies, the Council must do the same or be prepared to take the responsibility of refusing, for the Privy Council would be guided by law, and not by sentiment.

Sir W. FOSTER said that the question now before the Council was one of dry law, and not of sentiment. The principle had already been practically decided. He acknowledged that the Irish Society stood on a different footing from the English Society, but still it was a body which had the power to put a man on the Register, and it was not the province of the Council to deprive them of it. As the Hall had not been able to combine with other bodies, it was the duty of the Council to fill up the deficiency by appointing examiners. He considered that the case made out was strong enough to induce a majority of the Council to comply with the request.

Sir WM. GULL stated that he should exercise his discretion, and vote against granting the demand of the Apothecaries' Society.

Sir DYCE DUCKWORTH also expressed his intention of voting against the application.

Dr. HUMPHRY said there was no question of setting up a new examining body. The Apothecaries' Hall existed as the examining body under as good authority as any in the United Kingdom, and since the passing of the Act of 1858 it held a legal position on a par with all other licensing bodies in the country. By that act its licentiates were to be entered on the Register, and whoever was on the Register was a qualified practitioner in medicine and surgery. In his opinion there could not be any legal doubt as to the duty of the Council, and what had been done in regard to the English Apothecaries' Society should also be done in regard to the Irish Society.

The amendment was then put to the vote and lost by 21 to 8, after which Mr. Collins' motion was carried by 21 to 8.

A motion by Mr. B. CARTER, seconded by Mr. SIMON, was agreed to: "That the assistant examiners to be appointed for the Apothecaries' Society of London be examiners in surgery."

Mr. B. CARTER moved, "That these assistant-examiners be three in number."

Mr. SIMON seconded the motion.

Mr. MCVAIL objected to the motion, because no intimation whatever had been given of the number of students to be examined, or any information as to the mode of carrying out the examination.

Mr. SIMON said that for two years the Society had found that three examiners were sufficient.

Dr. M. DUNCAN asked what was the number of candidates.

Mr. B. CARTER said there were 250 annually, and the examinations were held weekly.

Mr. MCVAIL said that the Council were suddenly asked, without any information of a definite kind, to determine on the number of examiners. In his opinion three surgical examiners would not be sufficient for 250 candidates; and before arriving at a decision he wished for information with regard to the examinations—how the written examinations were conducted, whether there were any clinical examinations and who conducted them, and were the same three men to carry out the written, the oral, the clinical, and the operative examinations? It might be said that the average number of candidates was only five per week, but it would be a marvellous circumstance if that were the uniform principle throughout the year. Under these circumstances he would move as an amendment, "That the Council, instead of proceeding to adopt this motion, postpone action until it has received information regarding the methods of carrying out the details of the examinations, written, oral, clinical, and operative, and the numbers of students on the different days of examination throughout the year."

Dr. KIDD seconded the amendment, considering that the number three was either too many or too few.

Dr. BRUCE said that the Council, through its inspectors, would learn how the examinations were conducted, and until their report was received it would be prudent not to interfere too much with the Apothecaries' Society.

Sir W. FOSTER considered that the whole discussion arose from the fault of those who persisted in defeating his amendment on Friday last, when he asked the Council to wait for twelve months in order to give the Apothecaries' Society time to equip itself as a body capable of giving a complete qualification. In his opinion three examiners were sufficient to examine five candidates per week, and he hoped that the Council would carry the resolutions it had previously passed to their logical conclusion.

Dr. STRUTHERS said the recommendations required that two examiners should be present at every examination, but he would offer no further opposition to the Apothecaries' Society getting whatever they wanted.

Dr. HERON WATSON said, as the Council was about to establish a precedent, they should carefully consider the wise and prudent course to adopt under the circumstances. It would be very heavy labour for three examiners to deal with 250 or 300 candidates in the year. The number was too few to invest the written examinations with a sufficient degree of variety, and those gentlemen who prepared students for examination would soon become acquainted with the style of questions, so that the surgical part of the examination might come to be regarded as a matter about which the students need not distress themselves.

Mr. BRUDENELL CARTER said that during the last five years the Society had passed an average of 250 men annually. It was quite impossible to foresee what number of students would present themselves, or in what proportion medical students would be attracted from them by the conjoint examination of the Royal Colleges. This being the case, his proposition was merely this—that, inasmuch as for the last three years the surgical part of the examination had been conducted by gentlemen of the highest character and ability, who had not found themselves overworked for the present for the space of a year, it should remain *in statu quo*, though probably the examiners would feel it necessary to widen the field of examination, and if possible to conduct it with greater strictness than had been found necessary when the surgery was a mere accidental appendage with the qualification the Society was able to give. If the number of candidates increased, no doubt the Society would ask for a further addition to its strength, but at present such a step would be premature.

The amendment was negatived by 21 votes to 5.

The motion was then put and carried.

Mr. CARTER moved, "That each of these assistant examiners be paid an annual stipend of £100."

Mr. SIMON seconded the motion.

Mr. MCVAIL said the idea that 250 students were to be examined in surgery for £300 reduced the whole thing to an absurdity. Was it supposed that men would be found capable of doing the work who would give themselves up to it for that pay. Such a proceeding would make the whole examinations a sham. He moved, as an amendment, "That the question of remuneration be postponed."

Sir W. GULL thought that £100 was not such a despicable sum. He objected to bringing the matter down to one of trade measurement. There was a question of honour in the matter. It was an honourable position that a surgeon should be responsible for surgical knowledge, and in such a case the honour was to be looked at, and not the mere money reward. It was going on very unprofessional ground to say that it would be a sham to get men to examine for £100 a year in surgery.

Dr. STRUTHERS, from the Scotch point of view, thought the proposal a very handsome one.

Digitized by Google

Dr. HAUGHTON said that at Trinity College some of the surgical examiners were not paid at all, but those who were paid received on an average £1 a head. He therefore considered £300 for examining 250 candidates very fair remuneration. He entirely concurred with Sir Wm. Gull's idea. It was not requiring surgeons to turn out machines as they would steam-engines, but there was also the honour of the position to be considered, which would be worth more to the man than the sum he received.

MR. CARTER said it was the intention of the Apothecaries' Society to apply to Parliament for power to increase its fees. They felt that that which might be an adequate payment for a licence in one part of the profession was inadequate for a licence in all parts of the profession, and that the examinations must necessarily be more expensive. When that was done, then the payment to the examiners might be increased; in the meanwhile he hoped the existing arrangement would be permitted to stand.

The amendment not being seconded, the motion was put to the Council and carried by 20 votes to 1.

It was moved by Mr. CARTER, seconded by Mr. SIMON, and agreed to: "That, for a term of one year, from July 1st next, and subject to the orders of the Council, Messrs. Makins, Walsham, and Andrew Clark be appointed by the Council to be surgical examiners to assist the Apothecaries' Society of London in its conduct of its qualifying examinations."

Sir WM. GULL said a communication had been received from the London School of Medicine for Women, petitioning the Council that, in the event of their appointing examiners in surgery for the Society of Apothecaries of London, they would urge upon the Society the duty of recognising that school and admitting its students to the benefits of the Society's examinations and licence. He should be sorry if the application was passed over in silence. They could not do what they were requested, but he thought it would be right to pass a motion such as he had prepared—viz.: "That although the General Medical Council has no power to urge the duty of examining candidates, male or female, upon any examining body, and therefore cannot do more than receive the communication from the London School of Medicine for Women (Minutes, vol. 24, pp. 214-215), the Council are not unwilling to express the hope that examining bodies may, if within their powers, find it desirable to admit women on equal terms with men to the privilege of examination." He had no particular interest in the education of women, and had resisted it as long as he could in the University of London. But they had now come to the time when further resistance would be faction.

Dr. BANKS seconded the motion, and pointed out that, although women were not wanted as doctors in England, there was a very large opening for them in India.

Dr. QUAIN objected to the Council being asked to appeal to the Colleges with the knowledge that that appeal would certainly be refused. They had had a very recent lesson in that respect in regard to the appeal of the Apothecaries' Society to be admitted to the conjoint scheme. He moved the "previous question."

Mr. SIMON seconded the "previous question," which was put to the Council, and carried.

The Council then adjourned.

WEDNESDAY, MAY 18TH.

MR. JOHN MARSHALL, PRESIDENT, IN THE CHAIR.

Nearly the whole afternoon was occupied in appointing committees and arranging rules of procedure.

On the motion of Mr. Wheelhouse, seconded by Dr. Struthers, the Executive Committee was empowered to take the necessary steps for carrying into effect the clauses of the Medical Act (1886) relating to the registration of the diplomas of colonial and foreign practitioners.

A communication from the Parliamentary Bills Committee of the British Medical Association, relating to provisions of the Pharmacy Acts Amendment Bill, was referred to the Executive Committee.

Mr. MACNAMARA proposed: "That in compliance with the request contained in the last paragraph of the communication from the Science and Art Department, dated April 30th, 1887 (Minutes, vol. xxiv., pp. 229-230), the names of the medical bodies which have authority to give registrable diplomas or certificates for proficiency in Sanitary Science, Public Health, or State Medicine, be returned to the Science and Art Department as being 'genuine sanitary authorities,' which might wish to send delegates to the International Congress on Hygiene."

Dr. HERON WATSON seconded the motion.

Sir DYCE DUCKWORTH said that so far as the College of Physicians was concerned they refused to send delegates to such congresses because the Government would not pay the expenses.

Dr. GLOVER thought that the Council might itself send a direct representative.

The PRESIDENT said that any gentleman so sent would have to pay his own expenses.

The resolution was agreed to.

The Council then resolved itself into committee to consider the report of the Procedure Committee, and resolutions were passed to the following effect: That the Council should meet each year on the fourth Tuesday in May, and, if necessary, again on the fourth Tuesday of November, unless the President for reasons of public emergency should think otherwise; but other matters may be called on a written requisition signed by eight members and addressed to the President. That the Executive Committee should consist of eight instead of six members, four for England, two for Scotland, and two for Ireland, five being a quorum; and four meetings be held in the year on the Mondays before the fourth Tuesday in February, May, July, and November. Two new standing committees are to be appointed, the Education Committee and the Examinations Committee, each of which should consist of nine members, three for each division of the kingdom, to be annually elected on the nomination of the Branch Councils at the May meeting of the Council. It was also resolved that all the committees should be appointed annually at the meetings in May.

The Council having resumed, the resolutions passed in committee were agreed to, and to the Executive Committee was delegated the task of revising the Standing Orders, so as to bring them into harmony with the resolutions of the Council.

Mr. MACNAMARA hoped that the Council would before the present session terminated appoint visitors to the examinations, as he expected that in July examinations under the Conjoint Scheme between the Royal Colleges of Ireland would be held.

On the motion of Sir WM. TURNER, seconded by Dr. HAUGHTON, it was resolved, "That the General Council instruct the Branch Registrars to register, after the appointed day prescribed by the Medical Act (1886), graduates of universities who have passed a qualifying examination in medicine, surgery, and midwifery, either on the production of a diploma or diplomas in respect of medicine and surgery, or on the production of an authorised list of such graduates, duly certified by the University."

The Council then adjourned.

(*For continuation of Report see p. 1056.*)

"PLACENTA PRÆVIA."

To the Editors of THE LANCET.

SIRS,—Last year I recorded in your pages a case of entire placenta prævia which eventuated most happily to mother and child through the careful temporising measures adopted. That case was the last of four occurring in my obstetric practice during the last thirty years. I was, however, much struck by the perusal of your late article on this subject, and the aphorism you summed up the *pros* and *cons* with, and resolved, the next opportunity, to personally test its value. Strange to say, that chance was afforded me on the evening of May 5th. Mrs. W——, of this parish, was found on the floor in a state of collapse from very profuse hæmorrhage. This hæmorrhage had occurred at short intervals, but sparingly for three weeks. This, however, had not alarmed her or her friends much until this utter collapse occurred. I learned that she was about eight months pregnant. After giving some brandy and beef-tea and medical restoratives, I sent for my son (in practice about eight miles off at Sherringham), and whilst I gave the patient the A.C.E. mixture, he introduced his hand within the os uteri, detaching all the placenta adjacent thereto, pushing the rest to one side, and thus, after rupturing the membranes, placing the head *in situ*. Labour was rapid, and was expedited with short forceps. The child was dead, but the mother has done well.

I am, Sirs, yours faithfully,

Cley-next-Sea, Norfolk. W. SUMPTER, M.D.

THE LANCET.

LONDON: SATURDAY, MAY 21, 1887.

IN the second edition of our issue of last week, we were able to announce that the General Medical Council had determined by a large majority to consent to the application of the Society of Apothecaries for the appointment of assistant examiners to enable the Society to hold "qualifying examinations" in medicine, surgery, and midwifery. This decision will meet with the warm approval of the profession. Such opposition to it as was based upon the unwillingness to create multiple examining bodies had our cordial sympathy, for we have throughout recognised the disadvantages attending upon the existence of more than one licensing authority in London. There were, however, other considerations involved, and the Council have doubtless properly appreciated the obligations imposed upon them by the Legislature in complying with the request of the Apothecaries' Society, who, through no fault of their own, had been unable to combine with the other corporations. The Council, having arrived at this conclusion, encountered great difficulty in determining the steps which should be taken to give effect to the resolution they had already adopted. The whole question of the Council's position with reference to licensing examinations was raised, and it was held by some members that the responsibility which the Council was about to incur necessitated the appointment of assistant examiners in every branch of professional education. Motions were followed by amendments, which in their turn became substantive motions, again to be rejected by subsequent amendments which were proposed. The questions at issue were undoubtedly of extreme importance, and it is well that each aspect which they presented should be duly considered, but the conduct of the discussion, and the time which it occupied, gave but too clear evidence of the widest differences of opinion amongst the members of the Council. The question is certainly complex, and the Act is so drawn as to enable an interpretation to be put upon it which leaves room for doubt as to whether the Council have been well advised in the course they have adopted. The Medical Act of last year deals with two separate and distinct subjects. In the first instance a qualifying examination is defined as an examination in medicine, surgery, and midwifery for the purpose of granting a diploma, and this examination may be conducted by any corporation already possessing this right, or by a combination of two corporations, one of which is capable of granting a diploma in surgery, and the other of granting a diploma in medicine. Further, the Act puts upon the Medical Council the duty of maintaining the standard of proficiency required from candidates, and for this purpose empowers them to appoint inspectors of examination, who will make reports to be used subsequently for compelling the examining bodies to improve their method or for depriving them of their rights. When, however, any corporation is unable to enter into a combination for the purpose of holding a qualifying examination, notwithstanding that it has used its best endeavours, an entirely different course is adop General Medical Council are then authorised to ap examiners to assist at the examinations which are held by such corporation, and it becomes the duty of the assistant examiners to secure at these examinations the maintenance of such standard of proficiency in medicine, surgery, and midwifery, instead of the inspectors, whose services appear by the wording of the Act to be limited to watching the qualifying examinations conducted by the bodies mentioned in Section 3. It is therefore not an unreasonable contention of Mr. MCVAIL that the Council under these circumstances should take part in examination in the three subjects. The Council have, however, determined to limit their action to supplementing the wants of the Society of Apothecaries by the appointment of examiners in surgery only, and, whatever may be the intention of the Act, it is undoubtedly wise to interfere as little as possible at this mement in the Society's examinations. It may, indeed, be anticipated that the Society will wholly rearrange its examinations, and will strengthen its staff by the addition of men competent to deal with the various subjects. Should it fail to maintain a sufficient standard, the course of the Council is obvious; but interference in anticipation of failure would lessen the prospect that the Council and Society may usefully be employed together to the advantage of the profession.

Of other work which has engaged the attention of the Council may be mentioned the report of the committee on Dr. GLOVER'S proposals for amendment of medical education and the application of the Apothecaries' Hall of Ireland for the appointment of assistant examiners by the Council. To the former we shall hope to refer later; of the latter it may be said that there was no material difference between the position of the Irish and English Societies. The Council have, indeed, taken this view, and have agreed to comply with the application of the Apothecaries' Hall.

With reference to our remarks last week regarding the higher qualifications of the Universities and the Colleges, it is interesting to note that the Council resolved to "instruct the Branch Registrars to register, after the appointed day prescribed by the Medical Act (1886), graduates of universities who have passed a qualifying examination in medicine, surgery, and midwifery, either on the production of a diploma or diplomas in respect of medicine and surgery, or on the production of an authorised list of such graduates, duly certified by the University."

LAST week we published an account of two cases of Thomsen's disease, with remarks on the nature of the affection by Dr. BUZZARD. An interesting paper by Dr. JACOBY on the same malady is contained in the March number of the *Journal of Nervous and Mental Disease*. The disease is undoubtedly rare, and far more common in some countries—Germany and Scandinavia—than in others, though it is possible that slight cases may be of not unfrequent occurrence, and, not being very obtrusive, may have escaped the attention of the medical profession. So far as is known, Dr. BUZZARD'S are the first cases of the kind that have been seen in England. ERB has given a very thorough account of the disease in a monograph

Digitized by Google

published at Leipzig last year, and entitled "Die Thomsensche Krankheit" (Myotonia congenita). Good summaries of all the literature have been given in *Brain* in 1883 by Dr. PAUL CHAPMAN, and in 1886 by Dr. HALE WHITE. But for all this literary abundance, our actual knowledge of the true nature of the disease remains obscure, and though most authorities are inclined to regard the conditions as dependent entirely on muscular change, yet this view cannot be said to be altogether satisfactory. Tonic spasm catching the voluntary muscles as they are about to be put into action is the most characteristic symptom. The spasm may prevent altogether, or interfere but slightly with, the voluntary action; there appear to be all shades of difficulty of voluntary movement. But one point comes out very clearly, and that is that the spasm subsides after a variable period measured sometimes by seconds and sometimes by minutes, and then no further hindrance exists to voluntary movement until after a period of actual repose. The patient will have a difficulty in starting the pedals of a bicycle, but once he has thoroughly begun he may continue for hours without experiencing any impediment to the "paddling" action. Let him but stop for one brief rest, and the spasm will recommence with his fresh attempt at action.

According to most authorities the disease is necessarily congenital and hereditary, though it may not be manifested till very early youth, and generally is not very pronounced till adult life. In JACOBY'S case and in others the evidence of heredity was wanting. The muscles themselves are apparently splendidly developed, but there does not appear to be any actual increase of strength, so that though pseudo-hypertrophic paralysis may be suggested by the size of the muscles, yet the possession of fair strength and the retention in the vast majority of cases of the knee jerks are features sufficiently striking in contrast. Changes have been detected in the muscles in Thomsen's disease, and chiefly in the direction of great enlargement of the muscular fibres themselves, together with increase in the number of nuclei beneath the sarcolemma; and some assert that the connective tissue (perimysium of the muscles) is also augmented in amount. JACOBY says, "there can be no doubt that this disease is a congenital malformation of the muscular fibres," but it is surely open to belief that the muscular changes are secondary effects of the frequent tonic spasms. The influence of emotion in increasing the tonic spasm, and the prolongation of the same produced by energetic action of the will together with the inability quickly to relax the muscles by voluntary effort, whilst they could be equally explained on the muscular theory, might also point to a participation of central influences in the causation of the malady. The behaviour of the muscles to mechanical and electrical stimulation also differs from that which obtains in health. These changes were well marked in Dr. BUZZARD'S cases. The prolongation of contractions artificially induced, as by percussing the muscle, is the most noteworthy change. Indeed, it would seem that any stimulus to the muscle tends to set up an almost tetanic spasm, and, so far as these facts go, there would thus be much reason in ascribing the essential characteristic of the disease to the muscular apparatus alone. Although the disease is thus fairly characterised by its chief symptoms, yet many cases have been recorded which do not fully exhibit all the symptoms necessary to establish the diagnosis. ERB therefore classes the recorded cases in three groups: the first containing only purely typical cases, the second those which have a great similarity, and the third those which only show the myotonic disorder, but are complicated with other symptoms of nervous disease, it being essential to the diagnosis of Thomsen's disease that all other functions of the body and nervous system should be perfectly normal.

RINGWORM of the scalp is a disease of no great importance; it does not threaten life or even health, and there are plenty of remedies—so think many who have not had experience of it. The medical man who has had to treat it, however, regards it in quite another light; he knows well that in undertaking a case of ringworm of the scalp he will go through some anxiety in using active remedies and controlling their effects; that despite his best efforts with new remedies and methods, the disease will probably spread; that he will have difficulty in getting instructions efficiently carried out; and, finally, that the parents, becoming impatient at the long-delayed cure, will most likely seek further advice. He has, however, the consolation of finding that the results obtained are not much more brilliant than his own, and that the time expended in the "cure" leaves it doubtful whether this is due to remedies or the natural course of the disease. Parents who have had ringworm in their families look back on the time with a shudder; they think of the hair-cropping and shaving, the never-ending head-washing, the poulticing, the malodorous applications, the irritation and disfigurement of the child, the interrupted studies, and the long tedious isolation (often extending over a year or more) from playmates. Ringworm is equally trying to the poorer classes. They have to send their children to Board schools, where they contract the disease; during the earlier hair-falling stages, when it is easily recognisable, the patients are brought to hospitals, often in families, the poorest having to spend time and money in accompanying them; then, after attending some months, the hair crops up again, the disease drifts into the well-known chronic stage, in which only a few hair stumps and scales remain to betray the presence of the fungus; the children are thought to be well, and under renewed pressure by the Board-school authorities they return to school and spread the disease to others. This is going on every day at hospitals where such cases are treated. Of the thousands attending in the course of a year, probably not 3 per cent. are seen to their complete recovery. The time and trouble expended by doctors and patients, to say nothing of remedies, are little better than thrown away. Here, then, we have an exceedingly annoying disease, practically incurable in chronic stages, not difficult to diagnose, not depending on some obscure diathetic cause difficult to remove, but simply on the contagion of an easily recognisable parasitic fungus. With this knowledge we have allowed the disease to spread until it has gained such a hold on the population that it is to be met with amongst all classes and at every turn. Surely the time has come to make some organised stand. It may be suggested, with deference, that it is of the first importance that the appearances in the more chronic forms of ringworm of the scalp should be readily reco-

Digitized by Google

gnised. That this is not always the case at present is proved by the fact that children still suffering with the disease are frequently being certified as well or cured. It is these unsuspected chronic forms which are met with in families, at lodging-houses, at children's parties, and, above all, in schools. Medical men would do well to advise parents to send their children to schools where proper medical supervision is in force. For a reasonable fee any medical practitioner in the neighbourhood could act as referee; all fresh scholars should pass through his hands, and, most important, all scholars should be examined by him on their return from holidays. No scholar who had had ringworm should be permitted to return without a certificate. But all such effort will be of little use unless the School-board authorities will consent to give their help. No doubt there are difficulties in the way, but while no efficient means are taken may we not ask if it is fair to the poorer classes that they should be compelled to expose their children to contagion, or if it is fair to the community that Board schools should be permitted to become centres of infection?

AT the presentation-day on the 11th inst., Lord GRANVILLE, in making his annual speech as Chancellor of the University of London, touched full lightly on the educational questions which have been so thoroughly discussed in professional and academical circles, in the past year. The Chancellor is apparently unaware that there is in existence an Association for the promotion of a Teaching University in London; that University and King's Colleges are profoundly dissatisfied with being annexed to a University which requires no professional curriculum in Arts and Science, and so reduces these bodies to an equality with any so-styled college of a year's existence; that the Royal Colleges of Physicians and Surgeons are seeking a joint Charter to confer degrees in Medicine and Surgery, and are basing their petition on the fact that the present University only recognises the metropolitan medical schools as authorities to sign certificates, as in the case of provincial and colonial degrees, and gives them no power in the University of London. The opinions as to the proper functions of a real University expressed by Sir LYON PLAYFAIR fifteen years ago are now held much more absolutely than they were then, as the letters of Professor LANKESTER and Sir GEORGE YOUNG in *The Times* of the 18th inst. clearly show. It is now almost taken as an axiom that a university and an examining board have essentially different functions to perform, and, unless the latter is made subordinate to the former, that they require different organisations for their work. We regret to find that the Chancellor has not appreciated these differences in their full force. London requires a local university, such as exists in most provincial and colonial centres, and the fact that in London an Imperial examining board has been placed makes this necessity none the less urgent. The duties of the two bodies are as dissimilar as can possibly be imagined. A university has an assemblage of teachers for its rule and guidance; a purely examining board knows nothing of teachers, and only guarantees results. Both are valuable, but they cannot work side by side. The University of London has chosen the examination *rôle*, and it is impossible for it now to change its function. The modifications foreshadowed by the Chancellor will damage its present position, and not satisfy the desires of those who are anxious for a university on the old model. It is, indeed, very doubtful if Convocation will pass the new scheme, and anyone who is conversant with the attendance and debates in Convocation will readily see that a large university scheme for the metropolis should not be dependent on the casual attendance and votes of such a body. Important interests are at stake, and Convocation is not the body from which a fiat should issue. In the whole controversy two very different questions are intermixed—viz. (1) the best general teaching in Arts and Science in the metropolis, and how this is to be attained; (2) why medical students in London should not obtain degrees on the same conditions as elsewhere, even if the University of London persists in barring the way. A strong Royal commission would bring the numerous factors into a clear light, and in the present position of domestic legislation would probably be a necessary preliminary to settling the claims of the numerous bodies who are anxious to present, or to oppose, the petitions for Charters which are being prepared for the Privy Council.

Annotations.

"Ne quid nimis."

THE MEDICAL ACT, 1886: EXTRA PASS EXAMINATION.

IT has been decided to hold an Extra Pass or Final Examination on Friday, the 17th of June next, for the licence of the Royal College of Physicians of London and for the membership of the Royal College of Surgeons of England under the old regulations, in order that candidates who have completed the required curriculum of professional study may have an opportunity of obtaining the licence of the Royal College of Physicians or the diploma of Member of the Royal College of Surgeons in time to register under the conditions now in force, before the new Medical Act comes into operation (June 30th). Those candidates who were referred for three months in April last and those referred in January for not more than six months will, we are informed, be specially allowed to present themselves for re-examination on June 17th. Candidates should bear in mind that they must give fourteen clear days' notice in writing, stating the subject in which they desire to be examined, and whether for the licence of the College of Physicians or the membership of the College of Surgeons, to the secretary, Examination Hall, Victoria Embankment, London, W.C.

ALTERATIONS IN THE EXAMINATIONS OF THE UNIVERSITY OF LONDON.

THE calendar for the year 1887-88, which has been recently published, contains the numerous alterations in the examinations to which we referred when they were sanctioned by the Senate. Revised regulations and a revised syllabus for the Matriculation Examination will come into force in June, 1888. As a result of these changes, the length of the examination will be slightly reduced, *one* language only in addition to Latin and English will be demanded instead of *two* as at present, a separate paper in Mechanics will be set, and an option given between Chemistry, Heat and Light, and Magnetism and Electricity. But even more important alterations are to be introduced into the medical examina-

Digitized by Google

tions. At the examination for the M.B. degree, a practical examination of surgical patients at a hospital or at the University will for the future always form a part of the examination—in deference, we suppose, to the severe comments of the visitors from the General Medical Council. But in the changes introduced into the Intermediate M.B. Examination, the Senate has taken no advice, either from these critical visitors, from the examiners, or from the metropolitan teachers, and the result is a series of innovations which are universally condemned. In future, every candidate at the July examinations will have to choose between a Pass and an Honours paper in each subject; at the January examinations he will only be examined for a pass. If in July a candidate takes the honours paper, and cannot satisfactorily answer it, he will endanger his passing; and if he takes the pass paper, he shuts himself out from all chance of distinction. The only reasons for this proceeding which have reached us are that many candidates who have no chance for honours now send in papers, and so waste the time and patience of the examiners, and that the system works well at the Preliminary Scientific M.B. Examination. But we question if the examiners have recommended this change, or even been consulted about it. It was, we believe, in the pass examination that the examiners complained of the severity of the work, and this has been materially lessened by the appointment of assistant examiners, who obviously cannot be employed in determining honours. Again, at the Preliminary Scientific M.B. Examination honours are of but little value to medical students, whilst at the Intermediate M.B. the subjects are strictly professional, and the obtaining of honours in any given subject may materially affect the whole of the after career of a student. In every way these changes are most unfortunate, and show how far the authorities of the University can lose sight of the candidate in drawing up new regulations, and how necessary a Board of Studies is, so that a body in touch and sympathy with students may at least be consulted. As if in further emphasis of these remarks, the Senate has published a time-table for the coming examinations, which we should have thought impossible if it were not before us. The examination is to begin on July 11th—that is to say, before the medical session has even begun to draw to a close, and whilst lectures and practical classes in the subjects of examination are at their most important stages; and will finish on Aug. 4th, a period of nearly four weeks, during which time the student's physical energy will be taxed to the utmost and his mind be on the rack. A fortnight of this will be spent, not in the examination-room, but as an interregnum devoted to meditation on mistakes made in the papers, and in "cramming" for the *vivâ voce*. A more deplorable arrangement for the schools and the teachers, or one more trying to the candidates, could not have been devised. In January the same break of sixteen days has been introduced into the continuity of the examination, with a similar absence of reason.

EPIDEMIC MEASLES IN LEEDS.

MEASLES has recently shown exceptional general epidemic prevalence, and it appears from the recently issued Quarterly Return that the death-rate from this disease in England and Wales during the three months ending March last was higher than in the first quarter of any year since 1874. Leeds is one of the towns that has suffered most severely. The disease first became prevalent in this town about the middle of September last, and caused 230 deaths before Christmas; 137 more fatal cases were recorded in the first quarter of this year, and 15 more were returned in the first five weeks of the current quarter. Thus 382 deaths from measles have occurred in Leeds since the commencement of the epidemic in September last. The fatality of the present outbreak is the more remarkable, since the disease was severely epidemic in the borough so recently as the early part of 1884. The present epidemic of measles in Leeds has been more fatal than any since 1870, when the Registrar-General first began to issue mortality statistics for the large provincial towns. The recent exceptional fatality of the disease may be in great measure due to the unseasonably cold weather that prevailed during February and March, but relatively high rates of mortality from any of the principal zymotic diseases should always suggest special inquiry as to the sanitary condition of the suffering population. As regards the general death-rate in Leeds, it may be noted that in 1886 the death-rate, after correction for sex and age differences of population, was 23·4 per 1000; and that the town occupied the seventeenth place among the twenty-eight large English towns ranged in the order of their corrected rates of mortality from the lowest. The rate of infant mortality in Leeds that year, measured by the proportion of deaths under one year to registered births, was 181 per 1000. Tried by this test, Leeds took the twentieth place among the twenty-eight towns last year. The death-rate from the principal zymotic diseases in Leeds last year was 3·43 per 1000, against 2·88, the mean rate in the twenty-eight great towns, and, measured by this standard, Leeds took last year the twenty-first place among these towns, ranged in the order of their zymotic death-rate from the lowest. The mortality in Leeds from measles, scarlet fever, "fever" (principally enteric), and diarrhœa considerably exceeded the mean rate in the twenty-eight towns. Especially noteworthy is the fact that scarlet fever has in the last six years been nearly as fatal in Leeds as it was in the preceding ten years, whereas in other large towns, and in England and Wales generally, the decline has been most remarkable. These are among the considerations which point conclusively to unsatisfactory sanitary condition in Leeds requiring investigation and action on the part of the ratepayers and their sanitary authority. It may readily be proved that the health of Leeds, judged by its mortality statistics, has materially improved in the last twenty years; but it is fully as evident that, in comparison with other large towns, Leeds has in recent years been losing ground in the fortunately now general struggle for sanitary progress.

ADULTERATION OF DRUGS.

WE observe with satisfaction that Lord Coleridge and Mr. Justice A. L. Smith have decided, on appeal, that it is an offence against the Food and Drugs Acts to sell tincture of opium which differs materially in strength from that described in the British Pharmacopœia. It had been proved before the magistrate that the strength of the tincture sold was one-third less than that of the British Pharmacopœia, but the magistrate declined to convict. Many strange decisions have been given by magistrates in regard to the adulteration of drugs, and it appears evident that for this, as for many other reasons, the law requires amendment. It is unnecessary to insist on the extreme danger to public health which arises from weak or impure drugs. The effects of the most skilful treatment are often lost through the inertness of the drugs; and although we fully recognise the care and skill with which the great majority of pharmaceutical chemists do their work, it is necessary to guard the public against the dishonest minority. Moreover, the dispensing chemist, however careful and skilful he may be, is to a great extent at the mercy of the manufacturer, so that the public runs a double risk. Even the medical practitioner who dispenses his own medicines is exposed to the latter danger. He is often puzzled by the action or non-action of the medicine he is prescribing, when the fault lies entirely in the drugs. We hope to return to this subject before long.

A "PALACE OF DELIGHT."

THE realisation of Mr. Walter Besant's beneficent idea of a "Palace of Delight" in the East-end of London, set apart for the amusement and improvement of the toiling multitudes of that densely crowded district, is in itself a sufficiently notable event to claim a place in the chronicles of the capital; but when to this are added the felicitous facts that the opening of the Palace has been so timed as to constitute the commencement of the celebration of the Jubilee of Queen Victoria's happy and prosperous reign, and that Her Majesty herself performed the inaugural ceremony there, the event supplies material not only for the theme of the Court newsman, but for the hearty congratulation of every loyal subject of the crown which has been worn gracefully by a Sovereign who has laboured graciously for the good and contentment of her people for fifty years. The function on Saturday was all that could be desired, and, even by those cynics who do not believe in the spontaneity of reverence, and even affection, for a Monarch, it must be ungrudgingly conceded that the proofs of joyous emotion pervading the "masses" were not only abundant, but incontrovertible.

There is always great difficulty in forming an accurate forecast of the practical value and ultimate measure of success of any effort for the public good which is made for the people instead of by them. Whether this "Palace of Delight"—thing of beauty as it undoubtedly is, in many senses—will prove a joy for ever remains to be seen. We know how many well-conceived schemes have failed, at least in the full fruition of their expected results. It is needless, and might be invidious, to particularise; but the fact is beyond question, and the lesson it teaches ought to be submissively learned. The moral seems to be that there should not be overmuch *management* in the endeavour to meet the needs of the masses. Better far let taste develop itself, and then cultivate its growth. Attempts to "force" desired qualities in human nature generally fail, and not unfrequently more harm than good is done by the endeavour. Speaking generally, the scheme of the promoters of the "Palace of Delight" is an admirable one. It is satisfactory to find that the scheme of this new venture—which it would be most regrettable to ruin by any wrongheadedness—is sufficiently broad to include gymnasia and swimming baths. It might with advantage go further. Mr. Walter Besant's idea not only comprised, but made a feature of, dancing. Good might result from a reperusal of this gentleman's admirable and entertaining book. We commend the suggestion to the "o'er gude," who may, with the best intentions, frustrate the beneficent working out of this scheme, as they have marred many others. So far everybody is to be congratulated, and the event of Saturday last is one around which none but loyal and grateful recollections can cling.

THE BOILING POINT OF OZONE.

OZONE, according to the recent careful observations of Dr. Olszewski, boils at a temperature of − 106° C. This curious substance—the nature of which was so long a mystery, and about which so many conflicting hypotheses have been devised—is now becoming well known to us. For the sake of those of our readers who have not been able to follow the details of recent research, we may in a few words summarise the present state of our knowledge. Ozone is a denser form of oxygen. Its specific gravity is 24, that of common oxygen being 16, and that of hydrogen 1. It is highly probable that its molecules contain three similar oxygen atoms. In the concentrated state it is a powerful irritant poison, and it is very unstable, decomposing with explosion and with evolution of heat, and exerting a most powerful action on oxidisable materials. For some time past it has been known that it liquefies under the influence of combined cold and pressure. The liquid is indigo blue, and its vapour in a tolerably concentrated state has a colour which can only be compared to that of an Italian sky. Olszewski has now succeeded in liquefying it at the ordinary atmospheric pressure by exposing it to the intense cold of boiling oxygen (− 181° C.). When cautiously heated the liquid began to evaporate, and when heated to − 106° C. it entered into active ebullition. It is a very dangerous substance to work with.

SANITARY AUTHORITIES AND THEIR DUTIES.

A PAINFUL occurrence has taken place at Ince, near Wigan, in Lancashire. The authorities of Ince have had constructed lately an infectious disease hospital, and from the evidence given at the inquest on a child which was overlain by its fevered mother it appears that the nurse is sixty years of age, and she with her husband, who is fifty-five years of age, have charge of the institution. Mr. Brighouse, the county coroner, held an inquest on the child, and he, considering that the body was lying at a fever hospital and that many of the jurors were married men with families, dispensed with the practice of viewing the body. It came out in evidence that a case of typhoid fever was admitted into the hospital on a Saturday night, late, and that early on Sunday morning the patient gave birth to a child, which was the subject of inquiry. Dr. Hall, jun., who was acting for the medical officer of health during temporary absence from illness, and also the assistant of Dr. Hall, ordered the child to be removed from the woman. The father was appealed to, but he could not take it. The nuisance inspector and the clerk to the board, and also the relieving officer, were appealed to, but in vain, and, as might have been expected from so young a babe being left with a fevered mother, the child was found next morning overlain. The coroner, in summing up, stated that "the evidence, however, had disclosed a very unfortunate state of affairs. The woman in charge of the hospital was practically by herself, and this meant that for seventy-six hours she was kept awake nursing and attending to the wants of these people without any help. All the while communications were being made to the nuisance inspector and the clerk to the local board the woman was left by herself, and no provision seemed to have been made for clothing the child, who had been wrapped up in towels for want of something better. The whole case seemed to have been surrounded with neglect, and two questions to be considered by the jury were, first, as to whether the death was accidental, and then as to whether the management of the hospital was in any way to blame." The jury found a verdict of accidental death, and desired to say the hospital management was bad, and that "the authorities should reconsider the question of the management of the hospital so as to preserve life in the future." This is certainly an unfortunate case. Here we have a sanitary authority providing a hospital for infectious diseases, no doubt at the strong request of the Local Government Board, yet it is inefficiently equipped. Sanitary authorities will spend two or three thousand pounds in building a hospital, but, from a penny wise and pound foolish policy, will begrudge a couple of hundreds for furnishing it, and will grumble at the expense of a few pounds yearly for its proper maintenance. This case will probably teach the adjoining authorities that it is their duty not only to provide a hospital, but to see that it is properly administered, or how can poor people be expected to enter it? Nothing brings sanitary authorities to a sense of their duty so much as a misfortune like this, or a severe epidemic which slaughters hundreds. We would advise all medical officers of health either to have their infectious hospitals efficiently equipped or to have nothing to do with their management. We know the difficulties of providing and maintaining hospitals in

Digitized by Google

small local board centres and small towns, but surely a combination of adjoining places would always keep a hospital in use and enable one to be provided worthy of the name and maintained with proper efficiency.

AN UNUSUAL METHOD OF PROPAGATING INFECTION.

DR. A. TEPLIASHIN describes in the *Vrach* (No. 17) a curious epidemic of syphilis affecting the eyes of eight persons who came under his care in the hospital of the Glazovski district of the Viatski province. The conjunctiva was more or less inflamed and the edges of the lids thickened and hardened, with in some cases mucous patches in the neighbourhood of the eyes and mouth. In all cases mucous patches were found on the genitals or round the anus, but the patients entirely denied impure intercourse. As all of them came from two villages, it was evident that some cause must be in existence in their locality to account for this curious epidemic. At last it was discovered that a certain "wise woman" there had, in the exercise of her profession, which is one much esteemed among Russian peasants, treated all these patients for real or imaginary affections of the eyes by licking them with her tongue; this woman had syphilis, which it was interesting to learn had been communicated to her in the same way by another woman. The habit of licking out as much of the conjunctival sac as can be reached by the tongue is very common, Dr. Tepliashin says, in his province, and he is surprised that it does not oftener lead to evil results; but though he has been there during the last eight years, and has seen about 10,000 ophthalmic cases, he has not previously met with any syphilitic affections due to the habit. From subsequent observations made on the spot, it was found that no less than ten males and twenty-four females belonging to these two villages had been infected by the "wise woman." In order to combat the evil as far as possible, a temporary dispensary has been opened in the neighbourhood.

LONDON SEWAGE.

AT the meeting of the Metropolitan Board of Works, on the 13th inst., some further information was vouchsafed to the public in regard to the system of sewage disposal to which the Board has at last committed itself. Little is told which is new, and nothing which is likely to reconcile sanitarians or the public to the scheme, or induce them to accept it as a final solution of the problem. It is now settled that the whole of the London sewage is to be treated at Barking and Crossness, in spite of the very strong adverse opinion expressed in the reports of the Metropolitan Sewage Discharge Commission. The precipitation method adopted is, we think, a good one. It consists in treatment with lime and protosulphate of iron. The precipitate subsides in an hour or two, and a fair effluent is said to be obtained. The experiment, originally tried on a small scale at the Grosvenor-road station, was continued with much larger quantities at Crossness during last year. Nearly a thousand million gallons—that is, about nine million gallons a day—were treated. This yielded 30,614 tons of wet sludge, which on further settlement was reduced to 18,191 tons. Of this 16,747 tons were exposed to pressure in filter presses, and were thereby reduced to 5310 tons of sewage cake, two-thirds of the water being removed by the presses, about the usual proportion. It is said that about 3000 tons of the cake were taken without payment by farmers and others for manurial purposes. The rest, we presume, has accumulated. To all this we have only the old objection to make. The proposed system cannot produce a proper purification of the river. Even if it turns out that this is the best of all possible purification schemes, that the effluent is "fairly clear," and that the sludge and cake will produce no local nuisance, it still remains a fact that the situation of the works is utterly unsuitable. It seems to us doubtful, to say the least of it, whether chemical and mechanical operations upon the sewage of four million persons can be conducted without serious local injury, or at least annoyance; and we are certain that the effluent water, although much less objectionable than raw sewage, is unfit to be thrown into the Thames at the existing outfalls. At present, according to the Royal Commissioners, who had ample evidence before them, the river is polluted with sewage almost up to Teddington. The pollution will now be of a less disgusting character, but still it will remain a disgraceful pollution, to which the people of London ought not to submit. We have always maintained that the proper place for the treatment of London sewage is in Sea Reach, where there are large tracts of land for sewage irrigation, low lands to be raised, no houses to be incommoded, a large volume of water, and close proximity to the sea. To this remedy we shall surely come sooner or later, and then it will be found that the vast expenditure for works and steamers now lightly incurred by the Metropolitan Board of Works will have been absolutely thrown away. To those who wish for further information on the subject we commend the remarks of the Royal Commissioners.

FASTING AND POISONS.

THE advance of rational therapeutics will be characterised by increased precision in instructions as to the mode of taking medicaments, their relation to food, their state of dilution, difference of action according to temperament, and so forth. Fasting is already known to exercise an important influence on the effect of certain substances, and M. Roger has further investigated the influence of the state of hunger upon the power of animals to resist the poisonous action of alkaloids. It was found that such alkaloids as quinine, atropine, or nicotine, were only four-fifths as toxic if introduced during fasting into the peripheral venous system of a rabbit, as compared with their action when introduced whilst digestion is in progress. But if introduced into the portal venous system during digestion the toxicity is only half that during fasting. It is assumed, then, that fasting diminishes the power of the liver to arrest the alkaloid, and this coincides with a diminished power of glycogen formation. Sugar given to the animal three hours before experimentation causes the liver to recover its functions.

PIT WOMEN AND THEIR WORK.

IT is to us very satisfactory to learn that any necessary improvement in the condition of women employed in collieries is likely to be effected without entailing upon them the loss of their employment. The evidence afforded by the deputation of pit women which waited on the Home Secretary a few days ago is worth noting in this connexion. As far as its members were concerned, any detriment to health attributed to colliery labour appears to be imaginary, though we would not be misled by accepting these few selected examples as average types of their class. In the matter of domesticity, also, it is said that they and those whom they represent will stand favourable comparison with their sisters employed in factory work; while their working dress, if not conventional, is not indecent, and it is as womanly as the circumstances of their occupation allow. The hours of labour are not long, and a reasonable interval is allowed at meal times. In this respect, indeed, as well as the possession of a purer atmosphere and a somewhat higher scale of wages, they seem to be more fortunately situated than the majority of factory women. In one particular the women themselves admit that the work is unsuitable to them—

Digitized by Google

namely, their having to move railway waggons, a dangerous proceeding, which will probably hereafter be left in the hands of the men. With this exception they are well satisfied with their lot; and if no stronger evidence than has already been produced be forthcoming to prove their incapacity, the question of who shall work at the pit and who shall not can hardly, we think, be dealt with otherwise than by the process of natural selection.

EDINBURGH UNIVERSITY CLUB, LONDON.

SIR ALEXANDER CHRISTISON, Bart, M.D., presided over the last quarterly dinner of this Club, held at the Holborn Restaurant on Thursday, May 13th. Forty-one members and thirty-nine guests were present. The toast of "The Colonies," gracefully proposed by the Marquis of Lothian, K.T., Secretary for Scotland, was received with the utmost enthusiasm, and most eloquently responded to by Sir Saul Samuel (Agent-General for New South Wales), Sir Graham Berry (Agent-General for Victoria), and Sir Patrick Jennings (late Premier of New South Wales). Sir Dyce Duckworth proposed the health of the chairman. A specially interesting feature of the meeting was the presentation by Sir Edward Sieveking, M.D., on behalf of the Club, of a handsome silver candelabrum to Dr. J. B. Potter, on his resignation of the office of honorary treasurer, which he has held for a period of ten years, and in which his labours have been indefatigable and eminently successful, the Club being now in so satisfactory a financial condition as to be able to give a triennial prize of twenty guineas to the University of Edinburgh. Dr. Potter is succeeded in his important post by Dr. J. J. Pringle. Excellent vocal music was discoursed at intervals by Dr. Lavies and a party of friends. The Club now numbers nearly 400 members, and it is felt that this number might easily be increased. The honorary secretaries are Henry Rutherford, Esq., barrister-at-law, 2, Harcourt-buildings, Temple, E.C., and Surgeon-General W. Gerard Don, M.D., Junior Army and Navy Club, St. James's-street, S.W., either of whom would doubtless be glad to hear of Edinburgh graduates anxious to join the Club.

SMALL-POX IN AUSTRALIAN PORTS.

THE Board of Health of New South Wales have issued a report prepared by their President (Dr. H. N. MacLaurin) on the occurrence of small-pox, and the consequent quarantine measures which took place in connexion with the arrival at Sydney of the North German Lloyd's steamship *Preussen* on December 26th last. The steamer having embarked 544 steerage passengers as emigrants at Antwerp, called at Port Said on November 18th, and, although small-pox was prevalent amongst the Arabs there, the passengers were freely allowed to go ashore. The *Preussen* left Port Said on the 22nd, and on December 5th a passenger named Pryce sickened of small-pox. Early on December 15th the vessel arrived at Albany, but the health officer of that place refused to land the patient. So far as can be judged, no other person on board had up to this date contracted the disease, but, having regard to the history attaching to the vessel, all the passengers were landed and moved to the quarantine ground on her arrival at Sydney on the 26th. Small-pox showed itself amongst them on the following day, and there is every reason to believe that it was all contracted after passing Albany. The arrangements on shore appear to do credit to a quarantine station, for the patients can be at once thoroughly separated from those who do not sicken, and measures are taken to make the compulsory stay of twenty-one days as little irksome as possible. During this stay seventy-nine attacks occurred, and thirteen deaths resulted. The report deals specially with the circumstance that nearly all this disease would have been avoided if the first patient had been landed at Albany, and the President presses strongly for united action on the part of the several Australian colonies in the matter of quarantine detentions. That which renders quarantine measures necessary for small-pox in Australia is evidently the habitual neglect of vaccination, and some hope is expressed to the effect that the colony, learning how narrow has been its escape, will not neglect this precaution any longer. The lesson is a serious one, for out of nineteen of the passengers who had never been vaccinated, fifteen had small-pox, nine died, and one lost her eyesight; whereas, out of fifty-four said to have been vaccinated and some revaccinated, only four were attacked and none died. Of those who had previously had small-pox, three were attacked, but without death. We learn that the vaccination stations in Sydney and in the country districts are all but deserted, and the youthful population is described as "practically unvaccinated." We very much fear that the lesson which this incident should teach will largely be thrown away on the population. Experience in Europe has shown, whatever the disease to be dealt with may be, that true preventive measures are far more neglected in countries resorting to quarantine than in those who do not enforce it, and the extent of neglect may often be largely measured by the tenacity with which the quarantining of sick and healthy alike is maintained. The position of the Australian health authorities is admittedly a difficult one. They are powerless to enforce the true remedy against the spread of small-pox, and are hence thrown back upon the enforcement of a detention which affects large bodies of people not suffering from the disease, and which may at any moment, owing to error of diagnosis or otherwise, break down as a preventive measure.

TOXIC EFFECTS OF LEAD.

MR. WYNTER BLYTH has had an opportunity of examining portions of the bodies of two out of five persons who have at different times died more or less suddenly from, as it is believed, the effects of lead poisoning. In one case he separated about a third of a grain of sulphate of lead from the liver and about a thirteenth of a grain from one kidney, besides finding lead qualitatively in the brain. In the other he was able to examine the brain with more minuteness, and estimated that here the cerebrum contained about a grain and a half and the cerebellum about a quarter of a grain of sulphate of lead. Mr. Blyth went on to remark, in the paper he read to the Chemical Society of London on these investigations: "There has hitherto been no reasonable hypothesis to explain the profound nervous effects of the assimilation of minute quantities of lead, but if it is allowed that lead forms definite compounds with essential portions of the nervous system, it may then be assumed that in effect it withdraws such portions from the body; in other words, the symptoms are produced not by poisoning in the ordinary sense of the term, but rather by destruction—a destruction it may be, of important nerve centres."

THE TEMPERATURE OF THE SKIN.

THE experiments of Davy long ago demonstrated irrefutably that the temperature of the interior of the body varied little in man with race, climate, or season; yet it is familiar to all that the temperature of the skin varies considerably in different parts—the extremities, for example, and those parts of the skin in which the circulation is feeble being cooler than other parts. Quite recently some interesting experiments to determine these variations of the surface have been made by Professor Kunkel at Wurzburg. Taking the skin of the face in the first instance, he finds that in men from twenty to thirty years of age it varies from 85° to 89° F., with an approximate average of 88°. The skin of the more exposed parts of the body, as the tip of the nose and the lobules of the ear, in which the circulation is slow and

Digitized by Google

feeble, exhibited a lower temperature, not exceeding in many instances 75°, or even descending as low as 71·5°. The skin covering the muscular portion of the body is warmer than that over the bones and tendons. Contraction of the muscles caused the temperature of the superjacent portion of skin to rise one degree or more. The decrease of temperature from the skin to the outer covering in a room at a temperature of 63° was as follows: on the skin 88°, on the linen shirt 82°, on the vest 75°, and on the coat 72°. The highest temperature was found to occur in men in the full vigour of life. As a singular fact, Dr. Kunkel states that children otherwise in perfect health showed a much lower degree of surface temperature—from 77° to 84°—than adults. He does not appear to have followed out Professor Lombard's observations on the temperature of the head.

THE QUEEN'S JUBILEE.

ON the 16th inst. the Queen held a Court at Windsor Castle, at which, amongst others, addresses were presented by deputations from the University of Edinburgh and the University of London. The deputation from the former body consisted of Principal Sir William Muir, K.C.S.I.; Professor Campbell Fraser; Mr. T. Graham Murray; Dr. P. Heron Watson; the Right Hon. the Lord Advocate, C.B., M.P.; Sir Dyce Duckworth; Professor Sir William Turner; Professor Grainger Stewart; Professor Armstrong; and Mr. Taylor Innes. Sir William Muir, Professor Campbell Fraser, and Professor Sir William Turner had the honour of kissing hands. The University of London was represented by Earl Granville, K.G., Chancellor; Sir James Paget; Dr. Wood; Sir John Lubbock, M.P.; Sir William Gull; Dr. Quain; Dr. Weymouth; Dr. Baines; Mr. Osler; and Mr. Arthur Milman, Registrar. Earl Granville, Sir James Paget, and Dr. Wood had the honour of kissing hands.

GUY'S HOSPITAL.

THE *Graphic*, in its issue for the 14th inst., publishes a descriptive account of Guy's Hospital. The article, which is profusely illustrated, commences with a brief sketch of Thomas Guy, the founder of the charity, and traces the progress of the institution down to the present time. The illustrations are, on the whole, judiciously chosen, and comprise, amongst others, portraits of Guy and Hunt, the chief entrance, the chief clinical, Mary, and Dorcas wards, the founder's tomb, the old staircase, and the women's surgery, this last named indicating a tendency towards realism in art which we trust will not be allowed to go to such lengths as to rival the "pictures of horrors" of the Paris Salon. The publication of this brief history of the charity, and its labours by our contemporary cannot fail to attract support to the hospital in its attempt to retrieve its failing fortune.

PYO-PNEUMOTHORAX SUBPHRENICUS.

THE condition simulating very closely a pneumothorax of the right side, but which is due to an abscess between the liver and diaphragm, was first thoroughly described and differentiated by Professor Leyden. A record of such a case has just been made by Dr. Pusinelli of Dresden (*Berl. Klin. Woch.*, No. 20), who points out that the condition is mostly due to perforation of a gastric or intestinal ulcer, and that the diagnosis depends upon the occurrence of abdominal symptoms at the onset, the absence or complete suppression of pulmonary symptoms, the sharp transition from normal vesicular breathing at the apex of the lung displaced upwards by the diaphragm to amphoric breathing on deep inspiration, and the absence of hepatic dulness with marked displacement of the liver downwards. If the diagnosis be correctly made, it is urged that treatment might be directed to abdominal section, the discovery of the ulcer, and its excision. Duodenal ulcers, as the case he details shows, often run their course without symptoms, and may be so little adherent that a slight injury, as a fall on the abdomen, may detach them and cause perforation.

BAD DRAINAGE AND LANDLORDS' LIABILITIES.

BOTH in England and in Scotland it is being made clear to landlords that they will be held responsible for letting houses the drainage of which is in such a state as to induce injury to health amongst the tenants. The letting of a house for human occupation should necessarily imply that the house is held to be fit for occupation, and substantial penalty should be required of a landlord who fails to fulfil his part of the contract. In the case of Gurney *v.* Stroud, tried the other day before Mr. Justice Cave and a common jury, the judge informed the jury that if a house was let furnished, then there was an implied contract by the landlord that it was fit for habitation, and the tenant having shown that soon after he came into possession his wife and children became ill, two of the latter dying, he was awarded compensation to the extent of £175. And in a somewhat similar case which came before Mr. Sheriff Lees at Glasgow, £150 was awarded to a parent as compensation for the loss of a child eight years of age, and for illness in other members of his family, owing to the defective drainage of the house which he occupied.

PERFORATING ULCERS OF THE AORTIC VALVES.

FOR a few years past much attention has been given to the cardiac complications of tabes dorsalis, and every kind of view has been stated as to the possible connexion between the heart lesion and the spinal degeneration. Before the Société Nationale de Médecine de Lyon, M. Teissier exhibited a series of photographs designed to indicate the dimensions and nature of the perforations of the aortic valves observed in ataxic patients. These perforations are accompanied by an extreme thinning of the valve, such as is not met with either in atheroma or syphilis. M. Teissier considers it to be a genuine trophic change, a veritable perforating ulcer of the valves. Moreover, these lesions are found in conjunction with visceral perforations, also attributed to the tabetic influence—e.g., perforation of the trachea and of the œsophagus. In one of his cases of valvular perforation, M. Teissier observed an intestinal perforation the size of a franc piece. The holes in the aortic valves give rise eventually to all the signs of aortic regurgitation.

LIFE INSURANCE.

A CASE recently decided in the Court of Chancery may serve as a warning to any who purpose insuring their lives, and also as a caution to medical examiners. The defendant was alleged to have made a misstatement in having denied that he ever had rheumatism or heart disease, from both of which conditions he had suffered some years previously, and he consequently forfeited his policy and the premiums already paid by him. We do not now enter into the question as to how far a history of rheumatism or its cardiac effects ought to influence the acceptance of a life. Every case must be judged upon its own merits, though undoubtedly a rheumatic taint must often constitute a grave disqualification, notwithstanding the fact that since the introduction within recent years of improved methods of treatment, the dreaded cardiac complication is a less real danger than formerly. It is possible that the full meaning of the perversion of facts may not have been apparent to the offender, but the misstatement could not be condoned on that account. This kind of offence, though perhaps not common, might be illustrated

Digitized by Google

by more than one example. We have heard of a case of such downright dishonesty as the production by an albuminuric subject of a fluid other than his own for examination. There is therefore need both for the stringency of companies and for shrewdness on the part of their medical representatives in dealing with the question of life insurance among a certain class of applicants.

DISPENSARIES AND PROFESSIONAL ETHICS.

A GREATLY lauded panacea for the evils of gratuitous medical advice, we all know, is the establishment of provident dispensaries. At this very moment an influential committee, appointed by a public meeting, is considering the best means by which they can be established and encouraged in London; and we ourselves have always been anxious to see such institutions supported by the working classes. But great care is necessary to prevent their being worked in unprofessional ways. And we are constantly receiving circulars, handbills, &c., announcing these institutions and their arrangements and charges. The names of the members of the staff are often included. The general effect of the whole is not to convey a high idea of the value of medical services, or of the methods of competition in the medical profession. We invite expressions of opinion as to the best way of avoiding these evils. We all want to promote thrift and diminish the amount of gratuitous medical relief. The problem is to do so without degrading the medical profession and the popular estimate of medical services.

TYPHUS IN FLINT.

WE regret to learn that the outbreak of typhus fever in Flint still continues, and that it has been found necessary, owing to a sudden increase in the number attacked, to convert the assembly room at Flint Castle into a hospital. The circumstances attaching to this outbreak are very unfortunate. Typhus is so rare that it was hardly recognised as such in the first instance, and hence the disease tended to spread. Dr. Tegid Evans, the medical officer of health, we greatly regret to say, in the performance of his duties, contracted the disease and died. Since then Mr. Spear, of the medical department of the Local Government Board, has visited the town, and has advised the mayor and the corporation as to the action which should be taken to stay the spread of the infection. Fourteen fresh cases are reported to have recently occurred.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Bernhard Studer, formerly Professor of Physics and Geology in Berne, at the age of ninety-three.—Dr. Ludwig Rohden, director of the recently established Sea-bathing Infirmary at Norderney, at the early age of forty-eight, suddenly, at Gardone, Riviera, from the bursting of an aneurysm into the bronchus.—Dr. Hohl, Extraordinary Professor in the Science Faculty of Tubingen, at the age of eighty-one.

THE BOWER AND KEATES CASE.

THE profession will learn with satisfaction that there is some hope of its soon hearing the end of this case, which well illustrates the delay and the costliness of law. The committee charged with the duty of administering the funds raised to pay the legal expenses of Messrs. Bower and Keates met at Sir William Jenner's on Tuesday night, and reported the termination of litigation. A full statement of the principal facts will shortly be laid before the subscribers, who will be asked to empower the committee to distribute the balance which remains after paying expenses by contributing to the expenses of similar cases or to charitable purposes within the profession. Roughly it may be said that over £1700 were raised in little more than a week, and that a balance of about £500 is left after the payment of expenses.

SPECIALISM IN EXCELSIS!

WE have received a programme of the first annual meeting of the "Association of Genito-urinary Surgeons," which is being held this week at the Laurel House, Lakewood, N.J. The establishment of this Association has been attended with so much success, and commends itself so thoroughly to the more enlightened members of the profession, that many similar ones are shortly to be inaugurated! Among those more immediately to be promoted are associations of "Umbilicologists," of "Rhinologists," of "Tenotomists," of "Depilatory Surgeons," and of "Skin-grafters." The only reason we can perceive why this list should not be indefinitely extended is that surgery as an art would, by such differentiation, speedily be resolved into its constituent elements, and its professors broken up into repellent groups of solemn deliberators on the utility and beauty of the segregation of parts.

VICTORIA UNIVERSITY AND THE YORKSHIRE COLLEGE.

ON the 12th inst. the Yorkshire College made a formal application to the Court of Governors of the Victoria University to be admitted as a College of the University, and the application was referred to the Council for report in accordance with the provisions of the Charter. A further step has therefore been taken towards the fusion of the three colleges of Manchester, Liverpool, and Leeds into one great university, and we hope that no time will be lost by the Council in taking action towards the furtherance of the desired union.

THE BRUSSELS SCIENTIFIC CONGRESS.

THE Surgical Section of the International Congress of Science and Industry, which is to be held in Brussels next year, has given notice that instruments and apparatus of the following descriptions will be specially acceptable:—(1) Apparatus for the treatment of spinal curvature; (2) materials for dressings; (3) gynæcological instruments; (4) instruments for diseases of the urinary tract; (5) instruments for the treatment of glandular enlargements in the pharynx; (6) laryngological apparatus; (7) apparatus and dressings for antiseptic operations on the eye; (8) apparatus for the measurement of the acuteness of hearing.

THE PENJEH SORE.

AT the instance of the inspector of the military medical district of the Caucasus, a special commission has been appointed to proceed to the neighbourhood of Penjeh for the purpose of studying the etiology and characters of the so-called Penjeh sore. Dr. Rapchevski of St. Petersburg has been selected as director of the expedition. Some observations on this affection made by Dr. Suski, and communicated by him to the *Vrach*, were mentioned in THE LANCET of April 10th, 1886. This paper was subsequently (June 12th) referred to by Surgeon Pierson, who pointed out the identity of the Penjeh affection with the well-known Delhi boil, &c.; and, again, by Dr. J. Hickman (THE LANCET, Aug. 28th), who mentioned that he had also pointed out this identity in an Indian journal, and referred to a full geographical account to be found in Hirsch's Geographical Pathology, and also to an article by himself in the *Practitioner* of Jan. 1886.

THE APPOINTMENTS AT GUY'S HOSPITAL.

THE following are the Assistant-Physicians at this hospital:—Dr. Hale White becomes Senior Assistant-Physician; and, at a recent meeting of the governors, G. N. Pitt, M.A., M.D. Cantab., M.R.C.P. Lond., late Fellow of Clare College and present Demonstrator of Pathology at Guy's Hospital, L. C. Wooldridge, M.D., D.Sc. Lond., M.R.C.P. Lond., late George Henry Lewes and Grocers' Research Scholar, late Croonian Lecturer at the Royal Society and present Demonstrator of Physiology at Guy's Hospital, and E. C. Perry, M.A., M.B. Cantab., late Captain of the School at Eton, Fellow of King's College, Cambridge, and Senior Classic for 1880, and late Demonstrator of Anatomy at Cambridge, were elected to the three vacant Assistant-Physiciancies.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—The Medical Faculty are about to create a new Extraordinary Professorship of Laryngology in connexion with a Polyclinic for Throat and Nasal Affections, for which room has been taken in a private house in the Luisenstrasse. The first occupant of the chair will probably be Professor Bernhard Fränkel. A series of vacation courses intended for practitioners is being arranged. These are to begin on Sept. 26th, and will continue till the end of October.

Bordeaux. — M. Poueson, *agrégé* of the Faculty of Medicine, has been appointed Surgeon to the hospitals of Bordeaux. M. le Professeur Viand has recently read an important paper advocating considerable changes in the system of medical instruction, whereby the theoretical lectures would be given by the *agrégés* and the clinical instruction by the professors.

Cadiz.—Don Manuel Bernal has been appointed Professor of Medical Pathology.

Giessen.—Dr. Max Hofmeier, first assistant in the Royal Gynæcological Clinic in Berlin, has been appointed Professor of Midwifery and Gynæcology. Dr. Hofmeier has just married the eldest daughter of the late Professor Schroeder.

Halle.—Professor Olshausen's former pupils and assistants propose to erect his statue in the Gynæcological Clinic, which has been under his care for the last twenty-five years, as a mark of their affection for and gratitude to their old master.

Madrid.—Don Gabriel de la Puerta y Ródenas, Professor of Pharmacy, has been appointed a member of the Council of Public Instruction, in the place of the late Don Manuel Rioz y Pedraja.

Moscow.—Dr. Hugenberger, having completed his term of office as Director of the Moscow Lying-in Institution, has now retired. His successor will be Dr. Sutugin, *privat docent* in the Military Medical Academy, and one of the Medical Officers of the Duchess of Edinburgh's Hospital in St. Petersburg.

St. Petersburg.—Professor Wenzel Gruber, who has held the Chair of Anatomy for forty years, has resigned.

Würzburg.—One of the recently made Doctors of Medicine is, or was, a "post director," a captain, and a jurist, his age being fifty-six.

THE death is announced from Paris of the eminent French chemist, M. Joseph-Dieudonné Boussingault. The deceased, who was born in 1802, occupied the chair of Agriculture in the Paris Conservatoire of Art and Industry. He was named Commander of the Legion of Honour in 1857, and promoted to the rank of Grand Officer in 1876. M. Boussingault was the author of a large number of papers on physics and chemistry, and of treatises on "Chemistry and Physiology in Agriculture," "Studies on the Transformations of Iron and Steel," &c.

AN influential committee of the inhabitants of the Royal parish of St. Martin-in-the-fields is appealing for subscriptions towards the suitable celebration of the Queen's Jubilee. The money received will be devoted, either by direction of the donors or at the discretion of the committee, to any one or all of the following objects:—Entertainment to children and old people; the purchase of a site of freehold land for the extension of Charing-cross Hospital; a memorial window in St. Martin's Church; the Imperial Institute; and the Church House. A first list of subscriptions has already been published, and each of the above objects seems to be meeting with hearty support.

THE Editor of *Land and Water* has succeeded in inducing M. Pasteur to undertake an investigation into the cause of grouse disease, and asks those interested to co-operate with him in obtaining for the French *savant* the necessary specimens.

AT the last meeting of the Aldershot Military Medical Society, Surgeon-Major Scott, C.M.G., who has recently been studying the Pasteur system in Paris and Naples, gave an account of his investigation.

WE are asked to announce that all drawings to illustrate papers in the Pathological Society's Transactions must be sent to Dr. Coupland, hon. sec., before May 31st.

NEWS has been received from Vienna of the serious illness of Professor Billroth.

THE Cape de Verde Islands are stated to be now experiencing an epidemic of small-pox.

MEETING OF THE GENERAL MEDICAL COUNCIL.

(*Continued from page 1046.*)

THURSDAY, MAY 19TH.

MR. MARSHALL, PRESIDENT, IN THE CHAIR.

The PRESIDENT read a letter from Sir Henry Acland acknowledging the receipt of the address from the Council on his retirement, expressing his gratitude for the kindly feelings embodied therein, and adding that he should always take the warmest interest in all the future proceedings of the Council.

A communication was received from the Privy Council, stating that the Lords of the Council had yesterday passed an order for postponing until June 30th next the "appointed day" named in the Medical Act of 1886, and that the order would be forwarded as soon as printed.

Dr. STRUTHERS proposed the re-election of the existing members of the Executive Committee.

Dr. BANKS seconded the motion.

Mr. SIMON hoped that the members of the Executive Committee would be elected in the ordinary way by ballot, seeing that the Council had been strengthened by the election of five new members.

Dr. FERGUS said all that was necessary was to elect two new members, the existing members holding office till June.

After some discussion the motion was agreed to. A ballot was then taken for two new members of the committee, one for Scotland and one for Ireland, and the members elected were Dr. Heron Watson and Mr. Macnamara. The Business Committee, the Dental Committee, the Pharmacopœia Committee, and the Finance Committee (to which Dr. Humphry was added) were re-elected. The Education Committee and the Examinations Committee were also appointed.

Dr. QUAIN said that the available funds of the Council were exhausted, and there was nothing wherewith to pay the members for their attendance unless the English Branch

Digitized by Google

Council advanced it. They were willing to do so, but on condition that the Scotch and Irish Branch Councils made a remittance at an early period.

Mr. SIMON moved, "That the Council delegate to the Executive Committee to exercise the powers and discharge the duties of the Council so far as the Executive Committee shall, in the absence of the Council, find necessary or expedient, except as follows:—First, as to making representations or reports to Her Majesty in Council or to the Privy Council; secondly, as to making general rules or recommendations; and thirdly, as to deciding, under Section 29 of the Medical Act (1858), whether any medical practitioner has been guilty of infamous conduct in a professional respect."

Dr. HAUGHTON seconded the motion.

Dr. A. SMITH thought that all the offences under Sections 28 and 29 should be included in the exception.

Mr. SIMON thought the Executive Committee should have the power of removing from the Register persons who had been convicted of felony; but doubtful cases would probably be referred to the Council for decision.

Mr. MCVAIL saw no reason why the Executive Committee might not make "recommendations."

Dr. DUNCAN suggested that the motion should be deferred till the next meeting of the Council, considering the far-reaching nature of the change proposed.

Dr. HUMPHRY hoped that the matter would not be deferred. The Executive Committee should not have power to interfere with the general principles on which the Council acted, and that was sufficiently provided for in the exceptions named in the motion. It was important to enable the Executive Committee to decide many matters of business ordinarily undertaken by the Council. If that were done it was possible that one meeting of the Council in the year might be saved.

Dr. BRUCE supported the motion, and urged the importance of saving the time of the Council. Dr. Banks, Mr. Carter, and Dr. Heron Watson also supported the motion.

Dr. PETTIGREW thought the matter should be delayed in order that it might have more consideration.

Sir DYCE DUCKWORTH supported the motion, which was then put, and agreed to.

Dr. HAUGHTON moved, in behalf of the Irish Branch Council: "(*a*) That this Council do appoint two assistant-examiners to the Apothecaries' Hall of Ireland. (*b*) That these examiners do examine in surgery. (*c*) That for a term of one year, from July 1st next, and subject to the order of the Council, Sir William Stokes and Mr. Edward Hamilton be appointed. (*d*) That the fee to each assistant-examiner at the stated quarterly examinations shall be five guineas. (*e*) That, in the event of any vacancy occurring among the assistant-examiners appointed by this Council, it be remitted to the Branch Council in the division of the kingdom in which the vacancy has arisen to appoint an *ad interim* examiner or examiners."

Mr. COLLINS seconded the motion, which was agreed to.

Mr. MACNAMARA moved: "That the Council now proceed to appoint Inspectors of Examinations from the following list of persons suggested by the Branch Councils:—By English Branch Council: In Medicine—Dr. Coupland, Dr. Finlay; in Surgery—Mr. McGill, Mr. Pepper; in Midwifery—Dr. Malins. By Scottish Branch Council: In Medicine—Matthew Hay, James A. Russell; in Surgery—Joseph Bell, J. D. Gillespie, D. N. Knox; in Midwifery—A. H. F. Barbour, R. Milne Murray, W. L. Reid, James Stirton. By Irish Branch Council: In Medicine—John Magee Finny; in Surgery—E. H. Bennett, E. D. Mapother; in Midwifery—F. W. Kidd, T. M. Madden."

Dr. BRUCE seconded the motion, which was adopted.

The Council then proceeded to the appointment of inspectors in private, strangers being requested to withdraw.

On the readmission of strangers the PRESIDENT announced that the following gentlemen had been appointed:—For Medicine, Dr. Finlay; Surgery, E. H. Bennett; Midwifery, A. H. F. Barbour.

Dr. GLOVER called attention to the late appearance of the Medical Register, which he said was not published till April 29th. The Medical Directory appeared before the end of the previous year. In former years the Register appeared at various dates in February and March, but never so late as this year. No doubt the circumstances were somewhat exceptional, and certain improvements had been introduced, but he still thought that the appearance ought not to have been so late, and hoped that it would be earlier in future. He was quite sure that the fault did not lie with the Registrar, who took great pains to have the work done not only accurately but promptly.

Dr. QUAIN said that many changes had been required in the Register, and there were great difficulties in bringing out so large a volume. There had also been some delay in the Stationery Office, where the book was printed at a very cheap rate, so that it was impossible to put too much pressure upon them.

Dr. A. SMITH regretted that the matter had been brought before the Council, and thought that the attention of the Executive Committee ought to have been called to the subject. He also thought that there was an undeserved imputation of neglect on the part of the Registrar.

The REGISTRAR said that the work of the Register had materially increased of late years. Some delay had arisen in consequence of the useful addition of dictionary headings, which necessitated another revise. The work was done at a much cheaper rate than it would be done by an ordinary printer.

Sir WM. GULL thought that there ought to be a general expression of entire confidence in the Registrar. He had often been surprised at the admirable manner in which his work was done.

Dr. STRUTHERS expressed his concurrence in the remarks of Sir W. Gull. They ought to take no notice of the pellets of the penny-a-liners of the anonymous London press.

Mr. MCVAIL said he thought that Dr. Glover was entirely justified in the course he had taken.

Dr. GLOVER said he thought that he had carefully guarded himself in regard to their obligation to Mr. Miller, the Registrar. He still thought that he had brought an important matter before the Council. He was not quite satisfied that the late appearance of the Register was unalterable; and if it did not appear sooner next year he should feel it his duty to make the same complaint.

Dr. STRUTHERS, who had given notice of a motion for the consideration of the interim report of the Executive Committee and the suggestions of the Branch Councils in regard to the appointment of inspectors of examinations, said that it had been rendered unnecessary after the motion of Mr. Macnamara. He would only refer to one of the recommendations of the committee, that the inspectors should have their attention specially called to the quality of the examinations, and also to the sufficiency of the means and appliances for testing the qualification of the candidates. There was another matter to which special attention should be called—viz., the quantity of the examinations, that being a point in which they were deficient. There ought also to be a reference to the previous reports of visitors.

Dr. HAUGHTON withdrew a motion of which he had given notice, with reference to the manner of entering on the Register the names of British physicians and surgeons holding foreign diplomas in dentistry.

This concluded the business of the Council.

The PRESIDENT said he thought that the Council might congratulate itself on having settled some very important and difficult questions in such a way as to economise time and labour in the future. Though the session had been a long one, he did not regret the time that had been spent, because he thought that great economy and other advantages would be the result.

MEDICAL ATTENDANCE ORGANISATION COMMITTEE.

THE eleventh meeting of the above committee was held at 5, Lamb's-conduit-street on Tuesday, the 10th inst., Sir T. Spencer Wells in the chair. There was again a good attendance of the committee. The following resolutions were considered:—

1. "That it be an understanding that the resolutions passed on this branch of the subject—namely, relating to the hospitals—are intended as a basis for a conference with hospital authorities previous to the general report being submitted, and not as a final settlement." This resolution was carried unanimously.

2. "That in the opinion of this committee hospital authorities should be requested to consider the propriety of requiring all applicants for relief in the out-patient departments to sign a declaration that, in the case of single

Digitized by Google

persons, their average wages do not exceed £1 per week; and, in the case of a family, their joint earnings do not exceed 30s. per week."

To this resolution the following amendment was proposed:—"(1) That in the interest of hospitals, provident and other dispensaries, and of the poor themselves, it is desirable that an agent, well trained and thoroughly conversant with the locality, rates of wages, &c., be employed at general hospitals and free dispensaries to fulfil the following duties: (*a*) To ascertain whether the patients should receive advice and treatment gratuitously; (*b*) to make inquiries on the plan now in force at the London Hospital; (*c*) to refer persons ineligible for free medical treatment to local practitioners, provident dispensaries, or relieving officers. (2). That this proposal be adopted, on the understanding that all patients are eligible for first treatment, and also that those cases which are vouched for by the medical men as of special interest be retained at the hospital."

There was considerable discussion on the resolution and amendment, after which the amendment was carried by a large majority.

The following proposed alterations in the out-patient departments of hospitals was then moved by Mr. T. Holmes:—"1. That both the number of out-patients received each day and the hours for seeing them be limited, so that not more patients be received than can be deliberately attended by the stated officers of the hospital (and used for clinical instruction in hospitals having schools attached), and also that the present abuse of keeping patients waiting for a great part of the day be reformed. 2. That out-patients be not received (except in the casualty department) without a recommendation from some medical authority, whether a dispensary or private medical practitioner, so as to ensure that only persons are received whose medical condition fits them for out-patient treatment. 3. That out-patients be received only for consultation, and not for prolonged treatment, unless the latter be recommended both by the medical authority who sends the patient and by the out-patient physician or surgeon of the hospital. 4. That the casualty department be strictly limited to accidents and street emergencies, and that only accidents attend more than once."

It was resolved that these resolutions should be considered separately at the next meeting of the committee on Tuesday, the 17th inst.

TESTIMONIAL TO MR. FURNEAUX JORDAN.

A MEETING of subscribers to this fund was held on the 12th inst., in the library of the Birmingham Medical Institute, to present Mr. Furneaux Jordan with a Testimonial on the occasion of his retirement from the surgical staff of the Queen's Hospital and from professional life. Mr. J. St. S. Wilders presided, and a large number of the practitioners of Birmingham and the Midlands attended. The presentation, towards which 134 old pupils and friends contributed, took the shape of two large portraits of Mr. Jordan, which were specially prepared at the wish of the subscribers—one to be hung in the Queen's Hospital and the other in the Birmingham Medical Institute; and also a handsome library of books and a cheque for £217. The chairman, in making the presentation, alluded to Mr. Jordan's high renown as a surgeon and a teacher, and to the services he had rendered to his hospital and the profession. Sir James Sawyer, Mr. T. H. Bartleet, Mr. Chas. Sims, Mr. Vincent Jackson, and Mr. F. Underhill also added complimentary remarks; the latter, on behalf of the general practitioners, for whom he spoke, said that they had always found in Mr. Jordan the highest type of a consultant. Mr. Jordan, in replying, expressed his great appreciation of the kindness which had prompted the testimonial. He had been impelled to retire by considerations of health, as professional work could only be carried on by a strain too great for his endurance. He urged his professional brethren to consider whether it was worth while dying in harness,—whether they should not look forward to a short period of rest and enjoyment. Retrospectively, he observed that when he began life he was ambitious to take up the philosophical side of the profession, but he could not succeed in doing anything of the kind. He found practical surgery—the easing of the troubles and pains and anxieties of one's fellow-creatures—much more pressing.

SANITARY LEGISLATION CONFERENCE.

THE third meeting of the Conference convened by the Sanitary Assurance Association, to consider and report upon the Sanitary Registration of Buildings Bill, was held on the 16th inst., the President of the Association, Sir Joseph Fayrer, presiding. At the first two meetings the principle of the Bill was unanimously approved, and six out of the seventeen sections of which the Bill consists were with amendments agreed to. At the last meeting Section 7 was agreed to as follows:—The Local Government Board or corresponding authority shall issue licences in sanitary practice to the following persons and corporations—that is to say, (1) members of the Royal Institute of British Architects, members of the Institution of Civil Engineers, members of the Royal Institute of Architects of Ireland, members of the Association of Municipal and Sanitary Engineers, and surveyors and members of the Surveyors' Institution who are registered in accordance with this Act as qualified in sanitary practice; (2) architects and civil engineers who have been in practice three years at the passing of this Act, and who shall prove their practice has been a *bond fide* one and has included the designing and carrying out of constructive sanitary works; (3) sanitary associations incorporated by licence of the Board of Trade, provided that their certifying officers be registered as qualified in sanitary practice, in accordance with this Act; (4) medical practitioners registered as qualified in sanitary science; (5) persons who are medical officers of health at the passing of this Act; (6) persons who at the passing of this Act held appointments as engineers or surveyors under the Public Health Acts, provided they are members of one of the institutions mentioned in Subsection I. of this section; (7) such other persons as the Local Government Board or corresponding authority may consider qualified after examination. Considerable discussion took place on the eighth and ninth sections, but they were agreed to with merely verbal alterations, and the Conference then adjourned until the 23rd inst.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Reading Urban District.—The borough of Reading has increased between 1881 and 1886 from a population of 42,360 to 48,280, the persons per acre having risen from 20·2 to to 23·0. But the death-rate has fortunately fallen, and last year it stood at 16·8 per 1000; a substantial reduction has also taken place in the zymotic rate and in the infantile death-rate. All these points are brought out in considerable detail by Dr. Shea, who is also able to advert to some of the circumstances which have led to this comparative prosperity in health. The water supply is kept under constant and vigilant supervision, and improvements are steadily being effected in the method of its service. There is a sanatorium for small-pox, and a separate fever cottage. The notification of infectious diseases is also carried out under an Improvement Act, and the information so obtained has materially assisted the efforts to deal with these diseases. Bakehouses, cowsheds &c., slaughterhouses, and offensive trades are kept under supervision, and a code of bye-laws is now ready for application. Some occurrences of typhoid fever led to the water supply being suspected by some inhabitants of the district. Dr. Shea does not think the suspicion well founded, but he presses the importance of efforts to secure the diversion of all sewage about the intakes of the Reading Waterworks.

Reading Rural District.—This district is also under Dr. Shea's medical supervision. It had in 1886 a death-rate of only 12·2 per 1000, and the amount of infectious disease was unimportant. When any occurred, such action as was available was adopted to secure permanent improvement in the sanitary circumstances. The local water supplies are cared for, especially where dairy farms are concerned, and a system of scavenging has been adopted in one of the more populous localities.

Digitized by Google

Taunton Urban District.—In his annual report on this district Dr. Alford points to the improvements that have been effected in the water service, and which will soon be completed by the construction of a storage reservoir sufficient to ensure a constant service. Referring to complaints as to enforcing closure of wells, he states in answer that, whereas typhoid fever was once common in the district, it has now well-nigh disappeared. Much has also been done to improve the system of sewers and to secure adequate means of flushing. The corrected death-rate for 1886 was 17 per 1000, and the zymotic rate was only 1·4; infectious diseases being controlled by voluntary notification, isolation in hospital, and subsequent measures of disinfection. The sanitary hospital received 60 patients, the total admissions since its opening having been 593. Of the 60, 46 came from the urban district and 14 from the rural district, and, apart from two cases dying within forty-eight hours of admission, only two instances of death occurred. This hospital has always been worked satisfactorily, and a glance at the year's financial statement with regard to it shows that repayment by patients of the costs incurred is not allowed to stand in the way of the prime consideration of securing isolation in the interests of the health of the public.

Taunton Rural District.—In this district Dr. Alford has complaint to make as to the absence of proper means of drainage and as to defects in existing sewers, and he states generally that although good sanitary work has been carried out yet much remains to be done. The death-rate for 1886 was 15·9 per 1000. Bye-laws are needed to regulate the construction of new buildings, and power should be sought by the authority to make them.

Wokingham Urban District.—Here Dr. Shea reports a death-rate of 19·3 per 1000, but the zymotic rate was only 1·1 per 1000. Small-pox was the only disease that gave rise to anxiety, and the authorities are reminded that the Poor-law hospital is not properly available for sanitary purposes. The water supply is carried into houses needing it, the sewage farms work well, and bye-laws have been provisionally adopted.

Wokingham Rural District.—This district is also in Dr. Shea's area as medical officer of health, and the report is in the main a record of sustained sanitary work. Nine cases of enteric fever occurred in three houses, and a detailed account is given of their sanitary circumstances, the result being that these did not sufficiently account for the occurrence, which in point of causation remained somewhat obscure. The general death-rate during 1886 was 15·3 per 1000.

Whitechapel.—The death-rate for this district in 1886 was 22·5 per 1000, and Dr. Loane holds that it is considerably influenced by the number of common lodging houses within it. These tend at times to become suddenly filled by persons who are certainly not in the best state to withstand disease. Thus, early in the year when liberality was being dispensed at the Mansion House, there was a special influx of people into Whitechapel lodging houses from all parts of the country, and they were people who, whilst adding but little to the birth-rate, tend enormously to increase the sick and death rates. Indeed, whilst the common lodging-house births equal 1·3 per cent. of the total district births, and 38·4 per cent. of the births in the Union Infirmary, the deaths in these registered houses equal 11·9 per cent. of the total district deaths, and 64·5 per cent. of the total infirmary deaths. In this connexion it is interesting to note that in the Whitechapel district there are buildings constructed under the Artisans and Labourers' Dwellings Acts, and also by private enterprise, which accommodate some 6432 persons. These give a mortality of 16·0 per 1000, and contribute only 6·3 per cent. of the total deaths, or about half that which the common lodging houses contribute. And the contrast is the greater when it is remembered how large a proportion of young children to adults there is in the artisan class of dwelling.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5703 births and 3494 deaths were registered during the week ending May 14th. The annual rate of mortality in these towns, which had been 21·6, 20·6, and 20·9 per 1000 in the preceding three weeks, declined last week to 19·7, and was lower than in any previous week of this year. During the first six weeks of the current quarter the death-rate in these towns averaged 20·7 per 1000, and was 2·1 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 10·7 in Bolton, 12·8 in Derby, 14·9 in Leicester, and 15·3 in Sunderland. The rates in the other towns ranged upwards to 26·2 in Newcastle-upon-Tyne, 26·4 in Manchester, 26·9 in Liverpool, and 29·0 in Huddersfield. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 558, 529, and 548 in the preceding three weeks, declined last week to 500; they included 235 from measles, 136 from whooping-cough, 47 from scarlet fever, 33 from "fever" (principally enteric), 27 from diarrhœa, 20 from diphtheria, and only 2 from small-pox. No death from any of these zymotic diseases was registered during the week in Wolverhampton; whereas they caused the highest death-rates in Sheffield, Huddersfield, and Norwich. The greatest mortality from measles occurred in Sheffield, Manchester, Salford, Newcastle-upon-Tyne, and Norwich; from whooping-cough in Huddersfield, Birmingham, and Blackburn; from scarlet fever in Hull and Oldham; and from "fever" in Liverpool. The 32 deaths from diphtheria in the twenty-eight towns included 9 in London, 3 in Huddersfield, 2 in Liverpool, and 2 in Brighton. Small-pox caused 1 death in Portsmouth and 1 in Cardiff, but not one in Greater London or in any of the twenty-five other large provincial towns. Only 7 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; 3 new cases were admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 338 and 348 in the preceding two weeks, declined last week to 294, and were 48 below the corrected average. The causes of 74, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Cardiff, Bolton, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Sheffield, Salford, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·5 and 21·2 per 1000 in the preceding two weeks, rose again to 21·5 in the week ending May 14th; this rate exceeded by 1·8 the mean rate in the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 10·8 and 14·6 in Leith and Perth, to 23·6 in Glasgow and 23·7 in Edinburgh. The 536 deaths in the eight towns last week showed an increase of 7 upon the number in the previous week, and included 36 which were referred to whooping-cough, 15 to measles, 12 to scarlet fever, 7 to diphtheria, 5 to "fever" (typhus, enteric, or simple), 3 to diarrhœa, and not one to small-pox; in all, 78 deaths resulted from these principal zymotic diseases, against 95, 89, and 72 in the preceding three weeks. These 78 deaths were equal to an annual rate of 3·1 per 1000, which exceeded by 0·3 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 36 and 31 in the preceding two weeks, rose again last week to 36, of which 18 occurred in Glasgow, 7 in Dundee, and 6 in Edinburgh. The 15 deaths from measles showed a further considerable decline from the numbers in recent weeks, and included 10 in Glasgow and 5 in Aberdeen. The fatal cases of scarlet fever, on the other hand, which had declined in the five previous weeks from 11 to 2, rose again last week to 12, of which 6 occurred in Glasgow and 3 in Aberdeen. The 7 deaths from diphtheria also exceeded recent weekly numbers, and included 4 in Glasgow and 2 in Paisley. Of the 5 deaths referred to "fever," 2 occurred in Glasgow and 2 in Aberdeen. The 3 deaths attributed to diarrhœa were 10 fewer than those returned in the corresponding week of last year. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had declined in the preceding four weeks from 126 to 106, rose again last week to 120, and exceeded the number in the corresponding week of last year by 17. The causes of 56, or nearly 11 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 31·3 and 36·6 per 1000 in the preceding two weeks, declined to 24·4 in the week ending May 14th, and was lower than the rate recorded in any previous week of this year. During the first six weeks of the current quarter the death-rate in the city averaged 31·3 per 1000, the mean rate during the same period being but 18·4 in London and 20·1 in Edinburgh. The 165 deaths in Dublin last week showed a decline of of no fewer than 83 from the number in the previous week; they included 7 which were referred to measles, 4 to whooping-cough, 3 to diarrhœa, 2 to scarlet fever, 2 to "fever" (typhus, enteric, or simple), and not one either to small-pox or diphtheria. Thus 20 deaths resulted from these principal zymotic diseases, against 24 and 19 in the preceding two weeks; they were equal to an annual rate of 3·0 per 1000, the rates from the same diseases being 2·3 in London and 1·4 in Edinburgh. The fatal cases of measles, which had been 11 and 6 in the preceding two weeks, rose again last week to 9; the deaths from whooping-cough, "fever," and scarlet fever, on the other hand, showed a decline in each case. The deaths both of infants and of elderly persons showed a considerable decline from recent weekly numbers. Four inquest cases and 6 deaths from violence were registered; and 48, or more than a quarter, of the deaths occurred in public institutions. The causes of 19, or more than 11 per cent., of the deaths registered during the week were not certified.

THE DUBLIN DEATH-RATE.

The Registrar-General for Ireland, in a recent address, stated that, whilst a remarkable reduction in the death-rate had taken place in the English towns during the ten years which had elapsed from the passing of the English Public Health Act, no corresponding reduction had been noticed in Dublin during the ten years which had passed after the enactment of the Irish Public Health Act in 1874. This statement attracted the notice of the Dublin Town Council, and they adopted a resolution drawing the attention of Sir Charles Cameron, the medical officer of health, to the matter, and requesting him to report to the Council on the subject as soon as possible. That gentleman has accordingly drawn up a report, in which at the outset he states that since the corporation have been provided with adequate means for the purpose, they have, apparently with remarkable success, laboured to reduce the high rate of mortality which has so long prevailed in Dublin. It appears to him that a most serious factor in producing the high death-rate in Dublin is the poverty of a large proportion of the population. Another cause of the higher death-rate is the crowding into the city from the country of worn-out and decayed persons who end their days in the hospitals and workhouses. It is a remarkable fact that Dublin, with only one-twentieth of the population of Ireland, contains about two-fifths of all the hospital beds in the country. A fact showing the poverty of the people is that, while 15 per cent. of the deaths in the English towns take place in the workhouses and charitable institutions, in Dublin it amounts to 30 per cent. The returns of the Registrar-General for Ireland show that the death-rate among certain of the poorer sections of society is very great, while among the well-to-do classes in Dublin the mortality is the reverse of excessive. For example, in 1886 the death-rate was only 17·3 among the 30,129 persons composing the "professional and independent classes." Sir Charles Cameron thinks it probable that the stagnant condition of the contents of the city sewers operates injuriously upon the public health. It may not, he remarks, be generally known that the mouths of the sewers are closed for about twelve hours daily by the rise of tidal waters in the river; therefore, during this time all the sewage of the city is impounded in the sewers, except the portion which is pumped out at the two pumping stations. Until the beginning of 1879 the corporation of Dublin were unprovided with funds for the purpose of effecting needful sanitary reforms, and the following are the chief measures which since then have been taken to improve the sanitary state of the city. In 1880 £15,000 were expended in making and improving street sewers; a loan of £100,000 was obtained for paving the streets, and followed by a supplementary one of £13,000. In 1881 a loan of £28,000 was procured for domestic scavenging; and the following year the daily cleansing of the yards and sanitary accommodation of tenement houses was carried out. This service costs £3000 a year; and in 1882 an abattoir was established, at a cost of £15,000. Last year the second of two unhealthy areas was cleared, at a cost of £56,700; while public baths and wash-houses have been erected at a cost of £11,000, and a loan of £20,000 obtained for the erection of dwelling-houses for the working classes. Among minor sanitary loans may be mentioned £3000 for improvement of the sanitary accommodation of tenement houses, £2000 for the ventilation of sewers, and £3000 for pumping works in connexion with sewers; while three new streets have been formed since 1883, at a cost of £90,200.

THE SERVICES.

Surgeon-General W. S. Murray, M.B., has been appointed Principal Medical Officer with the troops in Egypt, vice Surgeon-General J. O'Nial, C.B., who will be placed on the retired list next month under the age clause of the Medical Warrant.

Surgeon U. J. Bourke has been appointed Medical Officer at the Royal Arsenal, Woolwich.

Deputy Surgeon-General J. Landale, M.D., has been appointed to the medical charge of the Sirhind Division.

Deputy Surgeon-General R. W. Meadows has been appointed Principal Medical Officer of the Western District.

INDIA OFFICE.—The Queen has approved of the following promotions among the Officers of the Indian Military Forces, made by the Governments in India:—Surgeon-Major William Smyth Fox, of the Madras Medical Establishment (dated Jan. 4th, 1887), and Surgeon-Major Abraham Nickson Hojel, of the Bombay Medical Establishment (dated April 2nd, 1887), to be Brigade Surgeons.

ADMIRALTY.—Staff Surgeon John Jolliffe has been awarded the Greenwich Hospital Pension of £50 a year for Fleet and Staff Surgeons, R.N., vacant by the death of Deputy Inspector-General F. J. G. T. Forbes.

In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Gerald Molloy has been placed on the retired list, with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated May 15th, 1887).

The following appointments have been made:—Fleet Surgeon Astley Cooper, to the *Dædalus;* Fleet Surgeon William D. Longfield, to the *Indus;* Fleet Surgeon Godfrey Goodman, to the *Royal Adelaide;* Fleet Surgeon James D. Smith, to the *Rupert;* Surgeon John L. Bagnall-Oakeley, to the *Royal Adelaide;* Surgeon John D. Hewood, to the *Minotaur;* Surgeon Edward J. Biden, to the Plymouth Hospital; Surgeon J. D. Trevor Roper, to the *Foxhound;* Surgeon R. Hickson, to the *Dolphin;* Surgeon W. G. Axford to the *Lion;* and Surgeon F. J. Burns, to the *Pembroke*, additional.

YEOMANRY CAVALRY.—Suffolk: Robert Harry Lucas, Gent., to be Surgeon (dated May 14th, 1887).

ARTILLERY VOLUNTEERS.—1st Cinque Ports: Acting Surgeon Thomas MacQueen, M.B., resigns his appointment (dated May 14th, 1887).

RIFLE VOLUNTEERS.—2nd Volunteer Battalion, the Gloucestershire Regiment: Surgeon C. F. Garrett resigns his commission (dated May 14th, 1887).—6th Lanarkshire: James Wylie, M.B., to be Acting Surgeon (dated May 14th, 1887).—1st Suffolk: Surgeon G. S. Elliston is granted the honorary rank of Surgeon-Major (dated May 14th, 1887).—1st West Riding of Yorkshire: Acting Surgeon T. Deville, M.D., resigns his appointment (dated May 14th, 1887).

THE VOLUNTEER MEDICAL STAFF CORPS.—The Manchester Division: Acting Surgeon William Henry Brownbill Crockwell, from the 16th Lancashire (3rd Manchester Rifle Volunteer Corps), to be Surgeon (dated May 14th, 1887).

THE Pharmaceutical Society held its annual soirée on Wednesday, in the galleries of the South Kensington Museum. The company were received by the President, Mr. Michael Carteigh, and members of Council. A selection of music was played by the band of the Royal Horse Guards, and a concert of glees and madrigals were given under the direction of Mr. and Mrs. Winn. The attendance was very numerous, and a very agreeable evening was spent.

THE annual Court of Governors of the Bath Mineral Water Hospital was held on the 2nd inst., when satisfactory general, medical, and financial reports were presented and adopted.

"Audi alteram partem."

THE COLLEGE OF SURGEONS' EXAMINATIONS.

To the Editors of THE LANCET.

SIRS,—As my name is prominently mentioned in your leader of last week upon the examinations at the College of Surgeons, perhaps you will allow me to reply.

I do not retract one word of the evidence I gave before the Royal Commission, and I still say that "one man may be lucky," &c.; and that "I do not know, human nature being as it is, how it is to be avoided." Of course, with a comparatively small number of candidates, as at Cambridge in former years when I examined there, it was possible for the whole of the candidates to pass before my surgical colleague and myself, who read *all* the papers and examined alternately *vivâ voce*. Such a method is impracticable at the College of Surgeons from the large number of candidates, as it is also at the University of London, where my surgical colleague and I divide the papers and candidates, and both of us only read all doubtful papers and examine *vivâ voce* all doubtful candidates, so that no man may be rejected by a single examiner. At the College of Surgeons the Court of "ten examiners of surgeons" is divided into five "tables," and the candidate whose paper goes, say, to A (where it is read and marked by *both* examiners), goes to B, C, D, and E for his *vivâ voce*, and so on. Hence each candidate appears before the whole Court, and no section knows what marks the others have given until they are called out at the end of the examination. It is, no doubt, much to be regretted that the rate of "pluck" has been so high lately—viz, 50 per cent. in January and 51·6 in April; but this is partly due to the fact that in January last 65 men were up for the second time, 23 for the third time, 7 for the fourth time, 2 for the fifth time, and 1 for the sixth time; while in April 60 men were up for the second time, 24 for the third time, 7 for the fourth time, 5 for the fifth time, 1 for the sixth, and 1 for the seventh time—making altogether 98 reappearances out of 246 candidates in January, and 98 out of 269 in April.

Although "the statements of 1881 hold good for 1887," a good deal has been done to improve the College of Surgeons' examination, with the object of gaining "less uncertainty," and even "in the way of diminished stringency." The former has certainly been attained to some extent by increasing the time allotted to the clinical and practical examinations respectively from ten minutes to a quarter of an hour, so that neither candidate nor examiner may be hurried. At the April examination, too, the experiment was tried of taking the two parts of the *vivâ voce* on different evenings, and thus a candidate had twenty-four hours to "pull himself together" after his first "heat." The rule has been established that the "tables" are rearranged every six months, so as to prevent colleagues getting into ruts; and a great deal of care is taken by the College officers in arranging the tables so as to counterbalance any recognised proclivities of certain examiners. Lastly, the practice of referring for only three months candidates who have failed by only one mark of the required fifteen (out of a possible thirty) has been introduced into the College of Surgeons', and through its representatives into the College of Physicians', examinations. As a set-off we have now the power to refer grossly ignorant candidates for nine and twelve months, and the following figures may be of interest:—In January 35 were referred for three months, 82 for six months, 4 for nine months, and 2 for twelve months; in April 43 were referred for three months, 79 for six months, 7 for nine months, and 9 for twelve months.

In conclusion, may I say that the Court of Examiners are but the servants of the Council, which does not hesitate to oust an incompetent examiner. The examinership is not now a life-long office, but is restricted to ten years' tenure, and at the present moment every member of the Court is in active practice as a surgeon and teacher. I could wish that more Fellows of the College would avail themselves of their undoubted privilege to attend the examinations and see how the work is done.

I am, Sirs, yours obediently,

May 16th, 1887. CHRISTOPHER HEATH.

"SUBSTANTIVE *VERSUS* HONORARY RANK."

To the Editors of THE LANCET.

SIRS,—Your article, and the letter of "A. M. D," in THE LANCET of the 14th inst., on the question of the rank of medical officers of the army, place this most unwise and undignified agitation in a true and proper light. Surely the medical staff has a substantive rank of its own. This is defined in such grade by the clear statement of the Secretary of State for War, that medical officers shall rank *as* the corresponding grades of military officers. What could be more explicit? To what end, then, can honorary rank be desired? Is it possible that physicians and surgeons, graduates of universities, Fellows and Members of Royal Colleges, seek to obtain incongruous military titles as prefixes to their names? If there be medical officers who desire such an anomaly, they have lost sight of the respect due to themselves as members of a learned and recognised profession, and they fail to appreciate the position that profession holds in the esteem of all cultured men. Medical officers may, I think, congratulate themselves that only a very few of their number are so strongly imbued with the love of playing at soldiers that they would carry the mimicry into the serious work of life; and it is fortunate that Mr. Stanhope's replies to questions on the subject are so definitely negative that no fear need be entertained that the few will succeed in placing the many in a very ridiculous position. I am, Sirs, your obedient servant,

May 17th, 1887. BRIGADE SURGEON.

To the Editors of THE LANCET.

SIRS,—Your issue of April 2nd, has just reached me. In it, at p. 701, is a letter by "F.R.C.P." That communication—doubtless written with the best of intentions—only too well illustrates the absolute ignorance on the part of our civil brethren of the peculiar position which we army surgeons bear in regard to what are two distinct professions—namely, those of *arms* and *medicine*. I can well understand the difficulty which "F.R.C.P." finds in appreciating the unanimous outcry of the army medical staff against the abolition of relative rank. When I first entered the service, some four years ago, the question of rank was often discussed among the medical officers. In those days no stronger opponent than myself existed against the tendency to ask for real or honorary rank. I took my stand—as "F.R.C.P." does—on the inherent position which that of surgeon gives to a man, and scouted all ideas of, or pretensions to, purely military titles, as being expressive of an undignified and false position for members of the medical profession. A few years of actual experience in the army has convinced me of the folly of my original views. I stand second to none in my respect and love for my profession, and have consistently and strenuously endeavoured to do my work as a good medical officer abreast of his times. In the army that is not enough to hold one's own, although it goes some way towards it. Once in the army, and mixing with army men, the value of military rank asserts itself. Let a man be ever so good a doctor, ever so good a gentleman (in its fullest sense), without rank—I mean military rank, and called by military terms—he is as no one. "If you go to Rome, you must do as Rome does." In the army you must be known by army terms and hold army rank. I write in no captious spirit; on the contrary, I may say I almost regret (being a surgeon) to write so. But the plain term surgeon or doctor is valueless in the army. Whether it is the reflected light from our civil rank and file, I know not, but *surgeon* as *surgeon* carries no weight. It is true we army surgeons are not soldiers in the sense of engaging directly in the operations of war, but we are an integral and important part of an army. On service we undergo the same hardships as the regimental officer; we run similar risks; our duties involve equal dangers to life and limb. We command our own men; we acquire the habits and qualities of the soldier. We have to combine units into disciplined bodies for the purposes of concerted action, and at the same time fulfil the offices and show the talents and judgment of experts. In a word, we are two professions rolled into one. I fail to imagine any higher *rôle* than that of the army surgeon. He is at once a commander of men, an organiser, and a guardian of man's most precious gift—*life*. The last few years have seen a steady increase in the ranks of the

Digitized by Google

army medical staff of well-trained, well-educated professional men—men not only adepts in their technical work, but at the same time men of varied talents; men not drawn exclusively from Ireland and Scotland, but men from the *English* schools. This last step of the War Office will check this popularity of the army as a career for able and educated surgeons. An inferior class of men only will enter. No man with any respect for himself or his profession could, or will, enter the army so long as his position is defined as being non-military, and as such secondary to each and every person whose rank is military. We want no blinking at the question, and hazy definitions of position and rank as given in Clause 125A of the last Warrant. If not *actual*, we want *honorary* rank in the army. The question is important, far more so than many of our civilian brethren think. We in the army know where the shoe pinches.

I am, Sirs, your obedient servant,

B.A. OXON., F.R.C.S. ENG.,
Punjab, India. Surgeon, M.S.

*** We fully sympathise with our correspondent in his opinion that a definite military rank is essential in the case of an army medical officer. As we have repeatedly said, the medical officers form an integral part of the army, and are entitled to, and must have, a distinct and clearly defined military rank. But we differ from him in this, that we believe the Warrant, as it is to be modified, will secure that well-defined position. The Royal Warrant in its amended form appears to us to grant a substantive military rank to each grade of military officers. If it should turn out—an event which we consider almost impossible—that the military authorities on any occasion call in question this rank, and the Secretary of State declines to carry out the assurance he has repeatedly given in his place in the House on the subject, we shall be found amongst the strongest supporters of any course which may seem calculated to secure to the medical officers that position to which they are clearly entitled. But, believing as we do that the War Minister will in good faith carry out the views he has expressed, we are of opinion that the positions of the medical officers will be well secured, and beyond the reach of question, under the modified Warrant.—ED. L.

A DOCTOR'S INCOME.

To the Editors of THE LANCET.

SIRS,—The letter I wrote you regarding the income of doctors has excited so much interest that I hope you will allow me further to discuss the possible remedies for the present deplorable state of things.

One of your contemporaries has suggested that 10,000 doctors should emigrate. But how can men emigrate who have no practical knowledge useful in that line of life, who have sunk their capital in their education, who have, perhaps, delicately nurtured wives and young children unfitted to rough it in the bush? I venture to assert that there is no overcrowding in the profession. There is one doctor to every 1550 people, which is none too many. The disease which blights so many of us is not want of work, but want of pay. Too many people evade paying the doctor, or pay him such fees that he cannot live decently. At shilling fees 1550 people ought to give a doctor over £800 a year, whilst I showed before that the gross income even of those who have practices scarcely exceeds £600. Surely this proves that the evil is not overcrowding, but underpayment. Can we remedy this? I will venture to offer some suggestions, though I fear they will be much opposed.

Taking fees in detail, we must own that *5s.* a visit and upwards are adequate payments for doctors. I think quite 10 per cent. of the population pay such fees. We will therefore disregard these. The next grade pay fees which range between *2s. 6d.* a visit and *5s.* These are as much as middle-class people can afford, and enable a doctor to make a fair honest living. These, too, may therefore be fairly set aside. I think they may be reckoned as constituting another 10 per cent. of the population. The remaining 80 per cent. pay, as a rule, such fees that no doctor can possibly live as an educated gentleman may claim to do, on these fees alone. The union, club, and dispensary patients pay, as I showed before, about *6d.* or *7d.* a visit, and the rest of the poor look on these as typical payments, and resent paying more. I will illustrate, by an actual case, the working of the present system, *ex uno disce omnes.* The wife of a retired tradesman joined a medical club, and fell ill. The doctor attended her. Her case was chronic and obscure. The doctor's visits fell to one a week, which the patient considered inattention. Another doctor was called in. This doctor charged *1s. 6d.* a visit (surely a modest sum for half an hour of an educated man's time). This was considered too heavy an expense. The woman obtained a letter for the local hospital and attended as an out-patient for some time. Becoming too weak and ill to go on as an out-patient, she reverted to her club doctor. Finally, she became an in-patient of the hospital, and, I believe, died there. She was attended throughout a long illness, with the exception of one short period, for the sum of *five shillings!* She did not expect a butcher to give her meat or a baker to give her bread for nothing, but that she should expend money on medical attendance seemed monstrous when two doctors were willing to see her for nothing, or next to nothing. Now why were these doctors willing to do this? The dispensary doctor was driven by sheer competition to accept these ludicrous payments or actually starve. The hospital doctor attended her for nothing, because his connexion with the hospital gave him status, and this enabled him to command higher fees from his private patients. But the system which *makes* the hospital doctor *breaks* hundreds of his less fortunate brethren. I would begin, then, by reforming the country hospitals. Let the general practitioner follow his cases to the hospital, and let him receive for so doing exactly the same fees as he would have received for attending the patient at his own home. Let the honorary staff be truly a *consulting* staff. Let them have the honour which they (rightfully) seek, but do not let them do general practitioners' work without pay. Let them meet general practitioners in consultation in the hospital over difficult or obscure cases.

Then we come to the present system of paying the holders of union and club appointments a fixed sum per annum. This has many ruinous effects. In the first place, the largeness of the total conceals from the patients the poorness of the pay. In the second place, it enables the doctor to mass several appointments and keep an assistant (often, alas, unqualified), almost always worse paid than any curate, to do the bulk of the work. In the third place, it often compels men to seek these appointments in order to exclude opponents, who would otherwise divide an already scanty income. Why should not payment be by result in all these cases? Suppose the fee were fixed at *1s.* a visit and *6d.* per bottle of medicine, with extras for mileage and nightwork. Let all members of clubs or parish patients be free to go to any doctor they chose who was willing to attend them at the fee fixed. In the case of clubs the patient might be required to pay a portion of each fee out of his own pocket, to guard against excessive visiting. In the great majority of cases union patients could similarly pay a portion of the fee and the parish the rest. I venture to say this system would not merely add largely to the present income of doctors, but would effectually disabuse the public mind of the idea that they have a moral right to a doctor's services for nothing. My arguments may have seemed to be all for the doctors, and none for the public. They are not so really. It cannot be to the advantage of the public that any trade or profession should work for nothing. Such a trade or profession would be *lean kine* eating up the *fat kine*—that is, the profits made by their fathers in other lines of life. A death-rate of 1122 in the medical, as compared with 842 in the legal and 556 in the clerical, shows an undue waste, which must injure the whole body politic. There is much actual loss, too, from scamped work. For instance, a club patient grew seriously worse through his doctor failing to visit him for four days. He then called in another doctor, who cured him in a few hours. Meanwhile the man had lost five days' work, of the value of *18s. 6d.*—as much as he had paid his club doctor in the past five years probably.

Now, Sirs, how are these reforms (or any others that may be thought better) to be brought about? General practitioners are like amœbæ—structureless, without differentiated brain or mouthpiece. Their nominal leaders really belong to a different profession, for consultants are to family doctors almost precisely as barristers are to solicitors. Where are we to look for leaders? Our next question will

Digitized by Google

be to form a combination such as has never yet been attempted by the profession. If that were once accomplished there would be no difficulty left. The union and club authorities would be obliged to accede to any reform demanded with anything approaching to unanimity by the profession. But there is the rub. We are not sufficiently organised to effect combinations. I fear, therefore, reforms are not likely, and that the present system of hard work and poor pay will probably flourish for many a long day, until, in fact, it has become so intolerable that there is a great dearth of candidates for the profession.

I am, Sirs, your obedient servant,

E. PAGET THURSTAN, M.D.

Southborough, Tunbridge Wells, May, 1887.

To the Editors of THE LANCET.

SIRS,—Kindly allow me to make a few remarks upon the letter of Dr. Paget Thurstan in THE LANCET of April 23rd, 1887. He says, "Such is the state of things; what is the remedy?"

There is and will be no remedy unless medical men hold more together. Why do we not have a society similar to the Incorporated Law Society, and determine amongst ourselves not to take any appointment without a meeting of medical men likely to be invited to undertake any appointment, consider the amount of work to be done, fix their own salary, not allowing the steward or secretary to say we give our surgeons "so and so," and then, throwing the result into the hands of the members, to ballot for the surgeon, each one honestly refusing to make any attempt to win over voters? Can there not be some interference on the part of the Medical Council to limit and determine the difference between medical men and chemists as to their several provinces? Numbers of the people, both rich and poor, *consult* chemists, and never send for a doctor until the eleventh hour, to save any difficulty with regard to the death certificate. Until this is done I fear there will be no remedy for the general practitioner.

I am, Sirs, yours obediently,

May, 1887. M.A. Cantab.

THE SOCIETY OF APOTHECARIES.

To the Editors of THE LANCET.

SIRS,—The decision of the Medical Council in reference to the Apothecaries' Society will give general satisfaction to medical practitioners throughout the country, and they cannot but feel very satisfied at the action of their representatives. The important discussion previously to the division will open the eyes of the medical world. Never was a speech made more damaging to the speaker, or more likely to poison the ignorant mind, than that of Sir W. Gull. One benefit, I trust, will arise from Mr. Brudenell Carter's able advocacy of the weak against the strong—namely, that now the Fellows and Members of the Royal College of Surgeons may hope to have his energy and ability directed towards obtaining for them their just rights and privileges from their own College. The Hall has now nothing to fear; and if in the future it sends out as good men as it has done in the past, the public and the profession will have no cause for complaint.

I am, Sirs, yours faithfully,

May, 1887. J. WICKHAM BARNES.

THE COMPULSORY DETENTION IN WORK-HOUSES OF PATIENTS WITH VENEREAL DISEASE.

To the Editors of THE LANCET.

SIRS,—In reference to the above subject, you state in last week's issue that a correspondent calls your attention to the fact that, so far as workhouses are concerned, such powers already exist, and are to be found in Act 30 and 31 Vict., the Poor-law Amendment Act, c. 106, s. 22. Now, when I wrote you fourteen days ago, I was quite familiar with Section 22, and, certainly, one might very well argue that it gives the necessary power; but I find there is considerable uncertainty as to whether it really applies to cases of venereal disease. It is therefore desirable to have a definite and authoritative opinion on the matter, and, if that be adverse, then some other measure must be obtained. In support of what I say, I may mention that quite recently a deputation of influential gentlemen from eleven unions or boards of guardians in the principal naval and military centres had an interview with Mr. Ritchie, President of the Local Government Board, with reference to the repeal of the Contagious Diseases Acts. In his reply, Mr. Ritchie referring to Section 22 of the above-mentioned Act stated: "Well, a question then arises as to what is the meaning of the words 'contagious diseases' in this Act. I have no doubt it might be argued, and argued with very great force, that the disease in question is a contagious disease under this Act; but I understand there is a very considerable element of doubt upon the point as to whether or not medical officers who are really responsible would be justified in certifying that a certain poor person is suffering from a contagious disease under the Act and ought to be detained." This really being the case, Mr. Ritchie proposed to submit the question to the law officers of the Crown, so that at present the matter is *sub judice*. Even when we obtain power to detain patients in Poor-law institutions, there still remains the large number of cases in lock hospitals and other hospitals with lock wards. Surely something should be done in order to deal more satisfactorily with these. I am, Sirs, yours faithfully,

May 17th, 1887. ARTHUR FLINTOFF MICKLE, M.B.

THE UTILITY OF DRUGS IN THE TREATMENT OF DISEASE.

To the Editors of THE LANCET.

SIRS,—I am a general practitioner, and am glad to be able to add have been a successful one for the past thirty years. I desire to make a comment or two on the speech of Sir William Gull at the last meeting of the Medical Council, as reported in THE LANCET of the 14th inst. I am referring particularly to his expressed disbelief in the utility of drugs in the treatment of disease, and his belief in the all-sufficiency of guarding the patients from any "interference with the powers of nature," and keeping him in "a warm bed." Sir William Gull, referring to the share which he bore of the responsibility of conducting the treatment of the Prince of Wales' attack of typhoid fever, stated that during the whole illness his Royal Highness did not take four doses of medicine. Typhoid fever, all properly educated medical men know, requires, as a rule, little or no active treatment. But what if the Prince's illness had been rheumatic fever or malarial fever caught in India (supposing his Indian tour to have taken place): would Sir William still have withheld all treatment by drugs—salicylates in the one case, quinine in the other? I will do him the justice to say I do not believe he would. But is it a fact that the treatment of the Prince consisted entirely in guarding him from interference with the powers of nature, and in keeping him in a warm bed? Was not alcohol freely administered? I do not know; but this I do know, that Sir William regards a full dose of alcohol, two ounces or even four ounces of brandy if necessary at bed-time, as the best sedative for the nocturnal restlessness accompanied by delirium which occurs in typhoid; and I would ask what is alcohol administered in this way but a drug? I am, Sirs, yours truly,

May, 1887. A GENERAL PRACTITIONER.

REPEATED ASPIRATIONS OF THE BLADDER.

To the Editors of THE LANCET.

SIRS,—The case of repeated aspiration of the bladder recorded by Mr. Collier in last week's LANCET is like one published in *l'Union Médicale*, Feb. 26th, 1876. The patient was a man seventy years old, who had retention from enlarged prostate. The bladder was aspirated with a Potain's aspirator sixteen times in nine days, and then at last an instrument was passed. He did well, and no harm came of the repeated punctures. "Yet who would have thought the old man to have had so much blood in him"!

Your obedient servant,

Wimpole-street, W., May 17th, 1887. STEPHEN PAGET.

Two entertainments by amateurs are to be given at the Novelty Theatre on the 3rd and 4th prox., under the patronage of the Prince and Princess of Wales and other members of the Royal Family, for the benefit of the Great Northern Central Hospital.

LEEDS INFIRMARY POST-GRADUATE CLASS.

(From a Correspondent.)

THE concluding lecture of a most successful course was delivered on Friday last by Dr. Barrs, on Albuminuria, after which Dr. Griffiths, the house-physician, gave a very interesting demonstration in urine tests. The value of this course to the hard-working country practitioner, and, indeed, to others whose time for reading is limited, and whose opportunities are necessarily restricted, will be at once seen by the subjects taken, which were as follows:—Coma and its Causes, by Dr. Clifford Allbutt; Common Deformities, by Mr. T. Pridgin Teale; Some of the Common Diseases of the Stomach and Liver, by Dr. Eddison; Intestinal Obstruction, by Mr. Jessop; Pulmonary Therapeutics, by Dr. Churton; Glaucoma, by Mr. Nunneley; Common Diseases of the Uterus, by Dr. Braithwaite; Gunshot Wounds, by Mr. E. Atkinson; Causes of Retention of Urine, by Mr. M'Gill; Common Diseases of the Larynx and Pharynx, by Dr. Jacob; Diseases of the Anus and Rectum, by Mr. A. Mayo Robson; Common Ear Diseases, by Mr. Hewitson; Injuries of the Head, by Mr. Brown; Syphilis, by Mr. Ward; and Albuminuria, by Dr. Barrs. After each lecture, demonstrations in the wards and in the post-mortem room have been a most valuable, practical, and useful part of the course. Immediately after the lecture a meeting of the members was held, presided over by Dr. Scott of Ilkley, for the purpose of discussing the desirability of a second course, the subjects to be treated upon, the remuneration of the lecturers, the desirability and practicability of admitting qualified men to clinical studies and operative surgery by payment of fee rather than by sufferance (this was introduced by one member, but voted out of order by the chairman), and other matters relating to the success of a future course. The meeting unanimously resolved that another course should be commenced, and that Drs. Barrs and Roberts, the honorary secretaries, who had so satisfactorily framed the last course, should work out and arrange the practical details of the future one, which is to commence on the second Friday in October next, when Mr. Wheelhouse is expected to give the introductory lecture. Although the late class was a comparatively large one (forty-one), there was a general belief expressed that many more gentlemen in the town and surrounding towns and district would take advantage of the next course. It was stated at the meeting that since the formation of the class it had lost two of its members: one by the sudden and lamented death of Dr. Murray of Burley-in-Wharfedale; the other by removal to London of Dr. J. Fletcher Little, late of Ben Rhydding, who, by his characteristic indefatigability, was largely instrumental in the formation of the class.

Before the meeting closed a vote of condolence with the widow of the late Dr. Murray was feelingly proposed, and a resolution passed that the class fee (£2 2*s.*) should be returned to his widow as a mark of respect to his memory. Very cordial and grateful votes of thanks were unanimously and enthusiastically accorded to the staff, specially including Dr. Griffiths, the house-physician, and to the honorary secretaries for their valuable services.

MANCHESTER.

(From our own Correspondent.)

HYDROPHOBIA.

THERE is some ground for fearing that rabies is on the increase in Manchester and surrounding districts. A fortnight ago two boys, who had been bitten by a supposed mad dog at Sale, were sent to Paris for treatment by M. Pasteur. It is satisfactory to note that yesterday, at the county police-court, steps were taken for putting in force the provisions of the Dogs Act throughout this division of the county.

BUILDING BYE-LAWS.

It was a short time ago stated here that the Sanitary Association was directing its attention to the unsatisfactory condition of the building bye-laws of the Corporation. A conjoint deputation from the Association and from the Architects' Society recently waited upon the mayor, urging their amendment in accordance with modern requirements, and there is ground for hope that this matter will now soon receive the attention of the City Council.

NEW SEWERAGE SCHEME.

The River Committee of the Corporation has just presented their report upon the new sewerage scheme for diverting the sewage from the river. It provides for a large and extended system of new sewers, by means of which the sewage will be taken some few miles below the city, and there treated with chemicals to precipitate the greater part of the solid matters, the effluent being still further purified by filtration through soil before it is allowed to flow into the river or into what will by that time probably be the ship-canal. When Manchester has thus set its own house in order, it will be in a position to call upon other offenders to cease polluting the river in its higher courses. The cost of these new works will be something like half a million of money.

ISOLATION IN INFECTIOUS DISEASE.

At the meeting of the City Council last week exception was taken by some members to the expenditure of £7500 for the isolation of patients suffering from infectious disease. The opposition was based upon two grounds: First, that with the exception of small-pox the sending patients with fever to hospital had in no way diminished the prevalence of these diseases; and, secondly, that it was wrong in principle to vote such large sums of money over the expenditure of which they had no control, as the fever hospital was under the management of a charity subject in no way to the supervision of the Corporation.

OWENS COLLEGE.

Owens College has come out very well from the recent pass examination of the College of Surgeons, and the percentage of plucks has not been large. Some few years ago it was the custom to institute a preliminary test examination (as is done in most of the London schools) before allowing men to go up for this examination, but during the late dean's (Dr. Gamgee) time this rule was abolished. The results do not appear to have been detrimental to the college successes. Owens College has lately benefited to the extent of £5000 under the will of Mr. Thomas Jones, who died at Bournemouth, but who formerly lived in this city. He has also made bequests to the Royal Infirmary, the Eye Hospital, the Southern Hospital, the Consumption Hospital, and to most of our local charities, amongst them to one that seldom receives recognition in this way—i.e., the Manchester and Salford Sanitary Association, to which he leaves £200—a most acceptable bequest, as the funds of this Society are not at all commensurate with the work it attempts to do.

THE SCARLET FEVER EPIDEMIC.

This epidemic appears to be slightly abating from the returns published weekly, but the wards of the fever hospitals are still very full of patients suffering from this disease, and measles prevails to an extent almost alarming. In the Chorlton Union alone last quarter 146 deaths were reported, and during the past month 85 deaths occurred in Gorton township. In other parts of the surrounding districts it is equally prevalent.

May 17th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE JUBILEE EXHIBITION.

THIS Exhibition, which was opened here on the 11th inst. by H.R.H. the Duke of Cambridge, under the most favourable auspices, may be said, as is often said here, "to have never looked behind it since." The registered attendance of visitors passing the turnstiles up to yesterday for the five days was 76,296, but as it was impossible to use the turnstiles completely on the first day, and many thousands were admitted otherwise and without counting, it is quite certain that already over 80,000 persons have been admitted. The firework display on the 11th was rather marred by the damp weather, but this has been more than made up for since by the brilliant illumination of the courts and grounds every night. In the exhibits several London houses are represented. In the stand of Messrs. R. McQueen and Son, surgical instrument makers,

Digitized by Google

of Newcastle-on Tyne, I noticed a respirator designed for the use of lead workers, by our townsman and late mayor, Mr. Henry Newton, surgeon. Mr. Newton has had much practical experience in the diseases common to lead workers, having been for a long time medical attendant to some of our largest works. The respirator is formed of wire work, with a filtering material capable of being changed with facility. It is distinguished by simplicity and economy in use, and it is therefore no wonder that the chief inspector of factories states "that it is the best thing of the kind he had seen, as it entirely obviates the objection to all other respirators—that of becoming so readily clogged." If Mr. Newton has been so fortunate as to devise a respirator to prevent lead poisoning he will become a public benefactor, for the destruction of health and life in white-lead works here and elsewhere is much to be deplored.

THE NEW FEVER HOSPITAL AT SUNDERLAND.

The foundation of the new Fever Hospital for the borough was laid on Saturday last. The site and building together will cost about £19,000. I will in a future letter give you a general description of the building, which is to contain every modern improvement.

POISONING BY NITRIC ACID.

Last Wednesday the wife of an umbrella maker at South Shields swallowed half an ounce of nitric acid mixed with quicksilver and water at seven o'clock in the morning. She received immediate attention, but died in four hours. The acid solution was used by her husband in plating umbrella handles. At Carlisle also a child has died after twenty-four hours' illness from swallowing nitric acid. The father of the child explained that he had the acid in the house to cure some disease in poultry, it having been recommended for that purpose by some newspaper.

TYPHUS IN THE EAST END OF NEWCASTLE.

Since I last wrote of fresh invasion three cases have occurred in one family and one single case in two other families; all these were removed to the hospital, with one exception (a case dealt with in private practice). One of the cases removed to hospital was the eighth and last member of the family affected. Two cases of undefined type, but strongly suspected to be typhus, have also been removed to hospital. In all of these cases disinfection has been fully carried out. Most of the cases have occurred in the City-road and Sheffield district.

Newcastle-on-Tyne, May 19th.

DUBLIN.

(From our own Correspondent.)

DUBLIN HOSPITALS COMMISSION.

IT is very uncertain whether the various recommendations and suggestions of the commissioners will be adopted. It is a report which will please but few people, and it was a great oversight, as has already been pointed out, on the part of the Government not to have selected at least one medical man as a commissioner, or at all events any important member of the committee connected with the Dublin Hospital Sunday Fund. The truth seems to be that the Commission was appointed to recommend a consolidation of certain of the Dublin hospitals, and also the redistribution of the annual Government grant, the words of the Warrant directing the inquiry to be held naturally leading to these suggestions. This being granted, no great surprise can be felt that the members of the Commission have reported in the way they have done.

VIVISECTION IN IRELAND IN 1886.

A return has just been issued relative to the number of experiments on living animals made in Ireland last year. It appears that the total number of persons holding licences were three, all being medical men, and that all the experiments were carried out in a painless manner. The experiments were seventeen in number, and were directed to the elucidation of diseases of the vascular and nervous systems and to blood poisoning.

HEALTH OF IRELAND.

During the March quarter the births registered numbered 29,054, and the deaths 25,392, the latter representing an annual rate of 20·9 per 1000. The birth-rate for the quarter was 1·0 under the average rate for the corresponding quarter of the past five years; and the death-rate shows a decrease of 1·2. Compared with the returns of pauperism, furnished by the Local Government Board, for the corresponding quarter of 1886, there was a decrease of 1073 in the average number of workhouse inmates on Saturdays during the quarter, and an increase of 2346 in the average number of persons on out-door relief.

The concert recently given in aid of the "Nurses' New Home," connected with the Adelaide Hospital, has realised a sum of over £50, which will be expended in furnishing the Home.

The salary of Dr. Oakshoot, assistant resident medical superintendent of Cork District Lunatic Asylum, has been increased by £25 a year.

J. Cardiff, M.D., has been elected coroner for South Wexford.

Dublin, May 17th.

BELFAST.

(From our own Correspondent.)

THE COUNTY ANTRIM GAOL.

THE Lord-Lieutenant of Ireland has appointed Mr. J. Camac Smyth medical officer of the county Antrim Gaol, in room of the late Dr. John Moore. Mr. Smyth was for some time house-surgeon at the Royal Hospital, where, owing to his kindly disposition and skill, he was a great favourite. For some time he has been acting as *locum tenens* for Dr. Moore at the gaol. The appointment is worth about £200 per annum.

BELFAST CHARITABLE SOCIETY.

I understand that at the last meeting of the board of this Society, one of the oldest charities in Belfast, a resolution was passed approving of plans for a new dining-hall, laundry, and other additions to the present buildings of the Society. The cost of the extensions will be about £3900. The President (Sir John Preston) stated that the board, while able to carry on this valuable work without an appeal to the public, would not forget that the constitution of the Society must be kept up by subscriptions, and he trusted the community would continue as hitherto to contribute to that charity.

BELFAST DISPENSARY COMMITTEE.

At the last meeting of this committee there was a very large attendance, as the principal business was the election of a medical officer for dispensary district No. 1, rendered vacant by the death of Dr. James Barron. There were eight candidates. After several polls the contest lay between Dr. John Barron and Dr. Taylor, the former of whom received 42 votes and the latter 35. The successful candidate is a brother of the late medical officer of this dispensary, who died some time ago of typhus fever.

Belfast, May 17th.

PARIS.

(From our own Correspondent.)

M. VULPIAN.

THE death is announced of Professor Vulpian, who is said to have fallen a victim to septic pneumonia, resulting from an anatomical inoculation. M. Vulpian was born in Paris in 1826. In 1854 he took the degree of Doctor of Medicine, and was then attached to the Museum, where he aided Flourens in his researches upon the nervous system. In 1860 he was successful at the *agrégation* with a thesis upon Infectious Pneumonia. Shortly afterwards he became one of the physicians of the Salpêtrière. The chair of Pathological Anatomy becoming vacant at the Faculty, M. Vulpian offered himself as a candidate, and, notwithstanding the opposition of M. Maret, dean of the Faculty of Theology, who denounced him at the Conseil Académique as an Atheist unfit to direct the education of the young, he was elected by a majority of one vote. A little later his adversaries carried the question to

Digitized by Google

the Legislature, laying a petition against his doctrines and teaching before the Senate. In spite of these attacks he remained one of the most popular professors at the School of Medicine, and after having been promoted in 1872 to the chair of Comparative and Experimental Pathology, he was elected in 1875 Dean of the Faculty. Already a member of the Academy of Medicine, the Academy of Sciences admitted him to their number in 1876, and only last year he was elected to the post of Perpetual Secretary, one of the highest honours to which a scientific man can aspire. As a physician M. Vulpian was not one of those practitioners who owe part of their reputation to public caprice. Of somewhat brusque manner, he was quite the opposite of the fashionable doctor, and his opinion was generally sought in obscure and difficult cases. It was M. Vulpian who was called to Frohsdorf for the late Count de Chambord, and it was not until his assent had been obtained that M. Pasteur ventured to inoculate the human subject in rabies. M. Vulpian leaves a large number of works upon medical science. Amongst these may be cited his "Leçons sur la Physiologie Générale et Comparée du Système Nerveux," his "Leçons sur l'Appareil Vaso-moteur," his "Clinique Médicale de l'Hôpital de la Charité," and, lastly, his magnificent "Maladies du Système Nerveux," beyond doubt the most original contribution to the subject in the French language.

DR. FLORAND ON AMYOTROPHIC SCLEROSIS.

Most neuro-pathologists recognise lateral sclerosis as a distinct systematic disease. Leyden of Berlin, however, maintains that the cases of amyotrophic sclerosis recorded by Charcot and others are merely varieties of progressive muscular atrophy and bulbar paralysis, which, in his opinion, are essentially the same disease. In a recent Paris thesis, prepared under the auspices of the eminent professor of the Salpêtrière by Dr. Antoine Florand, the objections of Leyden to the recognition of amyotrophic sclerosis as a nosographical variety are discussed and combated. Concerning the proposition that amyotrophic sclerosis is merely a variety of bulbar paralysis, M. Florand maintains—and this is the chief point of his thesis—that labio-glosso-laryngeal paralysis is one, and sometimes the only, symptom of lateral sclerosis. He thinks, moreover, that in the cases where Leyden did not note spasmodic symptoms these had either passed away or were yet to come; and he considered the muscular rigidity alone sufficient to establish the spasmodic character of these cases. Leyden's objection, that "for the lesion to be considered systematic it is necessary that it should be traced above the pons," is disposed of by a reference to recent researches by Kahler, Pick, Kojewnikoff, Charcot, and Marie, who have been able to follow the lesion of the pyramidal fasciculi through the pedunculi into the hemispheres.

ACTION OF THE LIVER ON POISONS.

M. G. H. Roger publishes the results of his researches with Professor Bouchard on the action of the liver on poisons. Having verified and confirmed the assertions of Heger and Schiff on the modifications which the alkaloids undergo in the hepatic parenchyma, M. Roger shows that the liver transforms also the normal poisons of the organism, including both the products of disassimilation, and the toxic principles which arise from intestinal fermentation. The most interesting and novel point is that the action of the liver on organic poisons only takes place in the presence of glycogen. This is established clearly in the different experimental diseases of the liver, particularly in animals in a state of inanition, where the gradual and parallel decrease in the two functions can be followed day by day. On the other hand, when hyperæmia of the liver is artificially induced by the injection of irritants into the vena porta, both functions are exaggerated; more glycogen is present and a larger quantity of poison is transformed. M. Roger thinks that the glycogen, changed into glycose, combines with the alkaloids, or with ammonia, to form new and less toxic products, such as he has obtained, outside the body, by heating mixtures of glycogen with alkaloids or ammonia in closed tubes. These experiments lead to various clinical deductions, which are reserved for a future memoir.

GERLIER'S DISEASE.

M. Haltenhoff, of Geneva, made a communication at the Academy of Medicine upon a new neurosis termed *vertige paralysant*, first observed by MM. Gerlier and David in agricultural labourers and shepherds residing in the vicinity of Geneva. This affection is characterised by attacks of paralysis of the muscles of the nape of the neck and extremities, with vertigo, lancinating pains, and ptosis. It occurs in persons living in hot and ill-ventilated stables, and is cured by a change of surroundings.

FOREIGN BODY IN THE PLEURA.

At a recent meeting of the Anatomical Society of Paris M. Leudet showed a preparation of the pleura of a patient who had been operated upon for empyema eight years previously. It contained an indiarubber tube a yard and a half in length.

Paris, May 17th.

VIENNA.

(*From a Correspondent.*)

THE PHYSIOLOGICAL CONNEXION BETWEEN THE HEART AND THE LUNGS.

PROF. ERNST VON FLEISCHL, the well-known Vienna physiologist, has recently put forward an ingenious view concerning the influence of the heart beat on the respiratory changes in the lungs. His theory is based on a very interesting, but hitherto unknown, physical phenomenon he had occasionally observed. If a liquid containing an absorbed gas be exposed to negative pressure—to a vacuum—only a small quantity of the gas absorbed can be extracted, ascending in visible bubbles through the liquid; but if the liquid had been shaken by a single blow or impact just before commencing the exhaustion process, nearly the whole of the gas absorbed is rapidly set free, the liquid assuming a froth-like appearance. The quantity of gas thus exhausted is one hundred times larger than that withdrawn without impact. This action of the impact on solutions of gases in liquids is, as I believe, somewhat analogous to the well-known phenomenon of rapid solidification of water cooled below the freezing point, or of instantaneous crystallisation of hot saturated and then slowly cooled solutions of Glauber's salt, also initiated by a sudden impact. At a recent meeting of the Vienna Society of Physicians I had an opportunity to see some of Professor von Fleischl's experiments, which can easily be repeated by means of a hypodermic syringe furnished with a stopcock. By a slow upstroke of the piston the lower portion of the syringe is filled carefully with water which has been exposed to the air for a short time; the orifice is then closed by turning the stopcock. The piston is now drawn upwards as far as possible, and then released slowly and cautiously until it touches the water again. By this exhausting action some gas bubbles are formed, which are to be expelled by opening for a moment the orifice and inverting the syringe. Then the liquid is shaken by a single blow exerted against the piston, or by releasing it suddenly. If a short time (half a minute) after the concussion of the liquid the piston is drawn upwards again as far as possible, the previously clear liquid becomes rapidly white, like an effervescent mixture, by the froth formed by the sudden and copious escape of the gas. In explanation of this phenomenon, Professor von Fleischl suggests that by the impact the physical connexion of the molecules of the gas and of the liquid is altered, and that the real solution of the gas in the liquid is transformed into what he calls a "molecular mixture," wherein the gas molecules, previously closely connected with the molecules of the liquid, are lying free in the interspaces between the molecules of the liquid, from which they can easily be withdrawn if the liquid is exposed a short time after the impact to a vacuum or to the process of diffusion. Now, the blood is also a liquid containing absorbed gases. The entrance of oxygen can be easily explained by the properties of the coloured blood-corpuscles, but the exit of carbonic acid has till now received no elucidation, for the rate of pressure of the alveolar air is not sufficient to secure the diffusion of the gas from the blood serum wherein it is dissolved into the air. The Professor assumes that the diffusion of the carbonic acid of the venous blood into the air of the alveoli is only made possible by the action of the impact imparted to the blood in the pulmonary artery by the systolic contraction of the right ventricle of the heart. By this impact the physical condition of the blood entering the alveolar capillaries of the lungs is changed, the solution of carbonic acid in the serum being converted into a "molecular mixture

Digitized by Google

from which the gaseous carbonic acid can diffuse freely through the alveolar walls into the air. He believes also that cyanosis is due to a weak action of the heart muscle, which cannot impart to the blood an impact sufficient for preparing it for diffusional exchange, so that its carbonic acid cannot be fully discharged. This view of the action of the heart on the respiratory changes seems also to be supported by facts of comparative anatomy.

Obituary.

CHARLES ROBERT THOMPSON, M.R.C.S., L.S.A.

WE announced a fortnight since the death, after a carriage accident, of Mr. Charles Robert Thompson, of Westerham, Kent. Such practitioners as Mr. Thompson was are not so rare in country districts as many imagine, but they are far too good to be allowed to disappear from the scene of their labours without a few words *in memoriam*. Those who knew Mr. Thompson even slightly, or who had had the pleasure of even casual relations with him at Westerham, saw quickly that he was a man of the greatest value to the neighbourhood in which he lived. His sound judgment, his large experience, his surgical readiness, and his kindly manner at once made themselves felt, and must be deeply missed by the community which he served so well, and that in succession to an honoured father who had practised in Westerham for over fifty years. Such histories are the very strength and glory of our profession. They constitute an influence in the surrounding country. Mr. Thompson served his generation in various public ways, notably as a churchwarden and as chairman of the Gas and Water Company. He was born at Westerham in 1830. He was educated at Romanoff School, Tunbridge Wells, and afterwards at St. Bartholomew's Hospital, where he took the Bartley Scholarship. His qualifications were those of the College and Hall, taken respectively in 1850 and 1851. He invented the tube trocar, now so much used in paracentesis. Mr. Thompson had suffered at times from attacks of angina pectoris. He leaves a widow, a son, and two daughters to mourn their loss. They may find satisfaction in reflecting on his life and character.

EDWARD NOLLOTH, M.R.C.P., F.R.C.S.,

RETIRED FLEET SURGEON, R.N.

IT is with regret that we record the death of Mr. Nolloth, which occurred on the 29th ult. at his residence at Camberwell. The deceased was the sixth son of the late John Nolloth, formerly Assistant Secretary of the Navy Board, and latterly of Portsmouth Dockyard. He was the first to be appointed on the staff of the Royal Naval Hospital, Malta; the second appointment being Mr. (now Sir Spencer) Wells. He was surgeon of H.M.S. *Victor Emmanuel* (eighty guns) during the whole of the Russian war, for which he obtained the Crimean and Turkish medals and Sebastopol Clasp, 5th Class Medjidie. He was buried in Nunhead Cemetery.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen have been admitted Licentiates of the College:—

Adams, Gerald Wheatley.
Adie, Alexander James.
Barker, Alleyne Hayward.
Barling, Arthur Stanley.
Barton, Francis Alexander.
Batchelor, Charles.
Blomfield, George Wills.
Bower, William George.
Brown, Frank Manson.
Brown, Lewis Henry.
Burke, Harry Morton.
Capes, Robert.
Charlesworth, George Henry.
Chilcott, Arthur Edward.
Cookson, Reginald George.
Comber, Arthur Wandesforde.
Davenport, Cecil John.

† Approved by the Examining Board.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 12th inst., the following gentlemen were appointed Examiners:—State Medicine: Dr. Francis S. B. F. de Chaumont, Edinburgh; Dr. Alfred Carpenter, London; Dr. Hubert Airy, Trinity; Sir Charles A. Cameron, Ireland. The following degrees were also conferred:—

DOCTORS OF MEDICINE.—Francis Murray Haig, Trinity; William Arthur Bond, St. John's.
BACHELOR OF MEDICINE.—Edward Noel Nason, Downing.
BACHELORS OF SURGERY.—Francis Murray Haig, Trinity; William Arthur Bond, St. John's.

SOCIETY OF APOTHECARIES.—The following gentlemen, having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates entitling them to practise as Licentiates of the Society on May 12th:—

Brodrick, H. E., M.R.C.S., Badwell Ash Hall, Bury St. Edmunds.
Crew, Henry Charles, Shaw-road, Dudley, Worcester.
Danvers, Herbert, Cape Colony.
Rutter, George Herbert, Lady Margaret-road, N.
Scott, Walter Frederick, St. Helen's Gardens, Notting-hill.
Strahan, Samuel Alex. Kenny, Berry Wood, Northampton.
Waites, Richard, Foulstone, The Grove, Ealing.

THE new premises of the City Provident Dispensary were inaugurated on the 16th inst.

KING'S COLLEGE HOSPITAL.—The bazaar in aid of the funds of this hospital has resulted in a net profit of nearly £1200.

MEDICAL MAGISTRATE.—Dr. E. Sparshall Willett of Isleworth, has been recently sworn in as one of the Justices of the Peace for Middlesex.

VACCINATION GRANTS.—The following gentlemen have received the Government grant for successful vaccination:—Mr. P. Swales, Sheerness (eighth time); Mr. J. W. Hayward, Whitstable, Blean Union (third time).

HOSPITAL SATURDAY AT BIRMINGHAM.—The amount collected on Saturday, the 14th inst., reached the gratifying sum of £6125 10*s.* 3*d.*, being contributions from the many workshops and warehouses of the town.

AT the sixth general meeting of the members of the Hospitals Association, held on the 11th inst., Sir Andrew Clark, Bart., President, in the chair, a paper was read by Dr. William Collier on "The Best Means to Prevent the Abuse of Hospital Charity."

DEVONSHIRE HOSPITAL.—The report of the Committee of Management of this institution for the past year states that 2459 in-patients were admitted and 2238 sent away as improved, 49 as no better, 24 at own request, 8 had died, and 121 remained on the books.

AT a meeting held at Plymouth on the 13th inst. it was decided to signalise the jubilee of the Queen's accession by the reduction or removal of the debt on the South Devon and East Cornwall Hospital. A committee was appointed to take steps to give effect to the resolution.

Digitized by Google

ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—On the 11th inst., at St James's Hall, Mr. G. A. Sala delivered a lecture on "What I saw in Australia and New Zealand," the proceeds of which are to be placed to the credit of the above hospital.

ST. JOHN AMBULANCE ASSOCIATION.—On May 14th Mr. Stephen Nockolds and his assistant, Mr. MacPhee, of West Cowes, were each presented with a handsome photograph album, by the members of the East Cowes Class, as a token of the esteem and regard in which they are held.

ST. MARY'S HOSPITAL: OPHTHALMIC DEPARTMENT.—We are informed that the eye department at St. Mary's will in future be open on Tuesdays, Fridays, and Saturdays, at 9 A.M.; Fridays being specially devoted to operations and selected cases.

On the 15th inst., a procession of Friendly and Trade Societies in the North-western district was held in aid of the University College and the North-west London Hospitals. A service was held at St. Pancras Church, Dr. Spence, Dean of Gloucester, preaching an appropriate sermon.

HOSPITAL AT DAMASCUS.—Dr. Macinnon, of the Scottish Medical Mission, has recently opened a hospital for poor patients at Damascus. The fanaticism of the Mohammedan population has forced the Government to close it, and Sir W. White is now making representations to the Porte to grant the hospital its protection.

A NEW SWORD HANDLE.—Prof. Braune of Leipzig, after a thorough investigation of the mechanism of the hand, has constructed a new sword handle on anatomical principles, which exactly fits the hand, and can be held with absolute security. It is expected that this improved sword handle will be found very useful, especially by cavalry.

BACTERIOLOGICAL LABORATORIES IN SIBERIA AND RUSSIA.—The Medical Society of Irkutsk, the capital of Eastern Siberia, will soon have a bacteriological station in this city of 40,000 inhabitants. The Kharkov Medical Society has received from the Kürsk Government Assembly 1500 roubles to establish a bacteriological laboratory in Kharkov, and will receive 700 roubles yearly to support the establishment.

SUNDERLAND NEW INFECTIOUS DISEASES HOSPITAL. The foundation stone of this institution, which is situated on an isolated site about twelve acres in extent, was laid on the 14th inst. The building about to be erected includes the administrative block, the laundry, and disinfecting establishment, mortuary, and two fever pavilions. The cost of the building is to be £14,796, and the price paid for the site was £5000.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—The annual dinner of this Society was held at the "Criterion" on Wednesday, the 10th, Dr. Alderson, President, in the chair. There was a large and representative gathering of the members, in addition to numerous guests of eminence in the profession and others. This Society, which was founded but a few years ago, has amongst its members many names well known in the profession, and has done good work during the session which is now passed.

QUEEN'S COLLEGE, CORK.—The following prizes and exhibitions have been awarded at the sessional examinations in the Faculty of Medicine:—Exhibition in Practical Medicine: William Kelleher. Exhibition in Practical Surgery: William J. O'Meara. Practical Anatomy: Third year—James Jackson and J. V. Ryan, equal (1st); E. Jenney and J. Wolfe, equal (2nd). Second year—Wm. O'Donnell (1st); J. Hennessy (2nd). Anatomy and Physiology: Third year—James Jackson (1st); J. Smith and E. Jenney, equal (2nd). Second year—W. O'Donnell (2nd); J. Tracey (3rd). Practical Physiology and Histology: J. Jackson (1st); J. Smith (2nd); J. Macpherson (3rd); J. Wolfe (4th). Surgery: E. Jenney (1st); J. Smith (2nd). Practice of Medicine: W. O'Meara (1st); W. Kelleher and J. Ryan, equal (2nd). Materia Medica: J. Hennessy (1st); W. O'Donnell (2nd); J. Tracey (3rd). Medical Jurisprudence: W. O'Meara (1st); J. H. Wilson (2nd). Midwifery: G. Jenney (1st); C. Porter (2nd); J. Smith (3rd). Practical Chemistry: J. Hennessy (1st); J. Ambrose (2nd); J. Tracey (3rd).

MIDDLESEX HOSPITAL.—The festival dinner on behalf of this hospital, announced to take place on the 18th inst., has been postponed.

CITY OF LONDON TRUSS SOCIETY.—The 80th annual festival in connexion with this Society was held on the 17th inst., the Lord Mayor presiding. During an existence of more than three-quarters of a century the charity has relieved over 425,000 of the suffering poor—9394 in 1886, men, women, and children. In the course of the evening the secretary announced subscriptions amounting to £610.

GREAT YARMOUTH HOSPITAL.—On the 18th inst. the Prince of Wales laid, with Masonic rites, the foundation stone of a new hospital at Great Yarmouth. The building, which will cost about £8000, is being erected on the site of a former hospital, and will consist of a central block of buildings, with north and south wings. Accommodation will be provided for forty beds.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At the monthly meeting of the members of this Association, on the 12th inst., a discussion took place on the regulations for dairymen and others under the Contagious Diseases (Animals) Act, 1886, and the Dairies, Cowsheds, and Milkshops Orders of 1885 and 1886. Several suggestions were made, and it was decided to forward them to the London Society, with the view of getting them incorporated in the new regulations.

THE LONDON HOSPITAL.—To-day (Saturday) the Prince and Princess of Wales, accompanied by their daughters, will open the new Nursing Home of this institution and the new buildings of the London Hospital Medical College, the cost of the latter being about £15,000. The Home, which has cost upwards of £10,000, provides separate sleeping accommodation for 100 day nurses and 50 night nurses, and is probably the most complete establishment of the kind in existence.

MEDICAL NOTES IN PARLIAMENT.

Registration of Dogs in the Metropolis Bill.

IN the House of Lords on the 17th inst. Lord Mount-Temple, in moving the second reading of this Bill, said the muzzle was generally regarded as a failure, and the object of the Bill was to provide that there should be a complete register of all persons who took out licences, each dog having a number to be worn on its collar.—Viscount Cranbrook did not oppose the second reading of the Bill, but suggested that further progress should be postponed until after the report of a commission on the subject, and investigation by committee. The noble lord said there were differences of opinion as to the origin of rabies from irritation and other causes.—Lord Belper stated that rabies, which had prevailed in Notts, had been checked by muzzling, but in a neighbouring county a poor boy was bitten by a mad dog and died. It was therefore desirable to give power to extend provisions against rabies beyond county border.—The Bill was read a second time.

On the motion of Viscount Cranbrook it was subsequently resolved that a Select Committee be appointed to inquire into and report upon the subject of rabies in dogs and the laws applicable thereto.

Monaghan Lunatic Asylum.

In the House of Commons on the 16th inst., in reply to Mr. P. O'Brien, Colonel King-Harman stated that arrangements are being made to have the necessary improvements carried out at the Monaghan District Lunatic Asylum. Diphtheria has not recently broken out, and one of the inspectors who visited the asylum towards the end of last March found the sanitary condition of the patients so satisfactory that only four out of the entire number of 485 were confined to bed.

The Army Medical Service.

In consequence of the lateness of the hour at which Dr. Clarke put his question on this subject on the 12th inst., in our last issue we were unable to give Mr. Stanhope's reply in full. The following, however, were the words used by the right hon. gentleman:—"I have said many times that the abolition of relative rank has not in any way altered the position or status of medical officers, and I have no reason to suppose that these officers are desirous of being called by titles so dissociated from the duties of their honourable profession as those of colonel, major, and captain. These titles are, however, necessary in the case of other departments, whose officers, unlike those of the Medical Department, do not belong to a recognised profession."

Poor-law Officers.

In answer to Mr. Waddy, Mr. Ritchie said that district medical officers and relieving officers are, speaking generally, appointed for life, subject, of course, to the proper performance of their duties, and their salaries cannot be reduced without their consent. It is not the case that there has been, on the whole, a great decrease in the number of paupers during the last few years, although, no doubt, in particular instances this has been so. Neither was it the case, in his opinion, that many of these officers are receiving salaries out of proportion to the duties they have to perform. He could not undertake to suggest that the Royal Commission on the Civil Service should extend their inquiries to the salaries of Poor-law officers, as this would be entirely beyond the scope of their

Digitized by Google

labours; but the question of the powers which should be possessed by Boards of Guardians with respect to their officers would receive consideration in connexion with the County Government Bill.

Typhus at Fort Burgoyne.

On the 17th inst., in answer to Mr. Bruce, Mr. Northcote stated that examinations have been made both by the Medical and Engineer Departments without discovering any cause which will account for the recent cases of typhoid fever at Fort Burgoyne. Arrangements have, however, been made for an independent examination by an expert of the Local Government Board, which might, he hoped, result in the discovery and removal of any insanitary conditions. Three companies of the 2nd Battalion East Kent Regiment were quartered in the fort until the 12th inst., when the battalion went to Lydd for training. It is intended if there be no objection on the part of the Medical Department, to accommodate the 4th Brigade of the Scottish Division Royal Artillery in Fort Burgoyne, so far as its construction will permit, the remainder of the corps being encamped close at hand.

The Status of Medical Officers.

On the 19th inst. Mr. William Corbet asked the Secretary of State for War whether he could state why army medical officers are placed on a footing with departmental or non-combatant officers, and disqualified from reckoning time on half-pay towards promotion or retirement, in view of the fact that they are required by the Regulations to go under fire, and, in time of war, do so.

The Secretary for War: There are several reasons why medical officers do not count time on half-pay towards promotion or retirement. In the first place, there is in their case no compulsory retirement (as in the case of combatant officers) at a comparatively early age, for it is desirable to retain the services of trained medical officers as long as possible. Moreover the retiring pay of medical officers is on a more liberal scale than that of combatant officers.

Births, Marriages, and Deaths.

BIRTHS.

BERRY.—On the 12th inst., at Queen's-road, Watford, Herts, the wife of F. Haycraft Berry, M.B.Lond., M.R.C.S., of a son (stillborn).

BREWER.—On the 17th inst., at "Cairo," Richmond-road, Hackney, the wife of Hampton Brewer, L.R.C.P.Lond., of a son.

DE'ATH.—On the 12th inst., at Buckingham, the wife of George Hanby De'Ath, L.R.C.P., M.R.C.S., of a daughter.

GRAHAM.—On the 14th ult., at Bindjey, Sumatra, the wife of John Campbell Graham, M.D., of a son.

HOWSE.—On the 11th inst., at 59, Brook-street, W., the wife of Henry G. Howse, M.S., F.R.C.S., of a daughter.

JOHNSON.—On the 12th inst., at Mickleton, Campden, Gloucestershire, the wife of J. Bovell Johnson, M.D., of a daughter.

KIDD.—On the 7th inst., at Brook-street, the wife of Percy Kidd, M.D., F.R.C.P., of a daughter.

MERSON.—On the 8th inst., at De-la-Pole, near Hull, the wife of John Merson, M.D., of a son.

STEEL.—On the 10th inst., at 11, Nevill-street, Abergavenny, the wife of William Dyne Steel, M.D., of a son.

MARRIAGES.

BURRELL—SPARKE.—On the 14th inst., at the Parish Church, Mansfield, by the Rev. Canon Pavey, John Burrell, eldest son of the late John Marchant, of Hertford, Solicitor, to Marion Guyse, second daughter of Geo. Whitefield Sparke, M.R.C.S.

HOLLINGSWORTH—COOPER.—On the 14th inst., at Southend-on-Sea, Thomas Smith Hollingsworth, Deputy Surgeon-General, retired, late of the 62nd Regiment, to Rebecca Page, third surviving daughter of Joshua Vernon Cooper, of Stoke Newington-green.

LEATHAM—RAWSON.—On March 22nd, at St. Mary's Church, New Plymouth, New Zealand, Henry Blackburn Leatham, M.R.C.S., to Mary Louisa, youngest daughter of Mr. District Judge Rawson.

NASH—PERCIVAL.—On the 12th inst., at the Parish Church, West Haddon, Northamptonshire, William Gunner Nash, M.R.C.S., L.S.A., to Louisa Gertrude, second daughter of Charles Percival Esq., of Fox-hill, West Haddon.

DEATHS.

BEGLEY.—On the 11th ult., at St. Peter's-square, Hammersmith, William Chapman Begley, M.D. Trin. Col. Dub., F.R.C.P., late Superintendent (Male Department) of the County Asylum at Hanwell, in his 85th year.

CROWFOOT.—On the 12th inst., at Beccles, W. E. Crowfoot, J.P., F.R.C.S., aged 80.

HUTSON.—On the 14th inst., at Erlegh, Whiteknights, near Reading, Henry Hutson, M.R.C.S., of Demerara, in his 66th year.

MENZIES.—On the 30th ult., on board the P. and O. steamship *Valetta*, between Colombo and Aden, Alexander Menzies, M.B., C.M., in his 26th year.

TIFFEN.—On the 12th inst., at The Limes, Wigton, Cumberland, Robert Tiffen, M.D., aged 63.

TROUTBECK.—On the 17th inst., at his residence, Finsbury-park (of acute inflammation of the lungs), James Troutbeck, M.B.Ed., L.R.C.S., aged 41.

WOODS.—On the 12th inst., at Heene Villa, Worthing, Francis Benjamin Woods, M.R.C.S., aged 77.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ARMSON, FRANK G., L.S.A., has been appointed Medical Officer for the Youall District of the Lichfield Union.

BRAILEY, W. A., M.A., M.D.Cantab., M.R.C.S., has been elected Consulting Surgeon to the Cardiff Eye and Ear Hospital.

DONNELLAN, PATRICK S., L.R.C.S.I., L.K.Q.C.P.I., has been appointed Medical Officer to the Anchor Line s.s. *City of Rome*.

DOUGHTY, DAVID SOMERVILLE, M.B., C.M.Edin., has been re-elected House-Surgeon to the Dumfries and Galloway Royal Infirmary.

DOWDING, ALEXANDER W. W., M.D. Durh., M.R.C.S., has been appointed Medical Officer for the Fourth District of the Stow Union.

HESLOP, W. J., F.R.C.S.Ed., has been appointed Medical Officer of Health for the Stretford Rural Sanitary District, vice Geo. Pettinger, deceased.

KERR, JAMES, M.B., C.M.Ed., has been re-elected Surgeon to the Dumfries and Galloway Royal Infirmary.

KILHAM, CHARLES S., M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer for the Fourth District of the Ecclesshall Bierlow Union.

MACDONALD, ALEX. DALL, M.D., C.M.Ed., has been re-elected Physician to the Dumfries and Galloway Royal Infirmary.

M'LEOD, P. B. H., M.D., C.M.Aber., has been reappointed Medical Officer by the Parochial Board of New Deer, Aberdeenshire.

MANN, ALFRED, M.B., C.M.Ed., has been appointed Visiting Surgeon to the Chester General Infirmary.

MARK, LEONARD, L.R.C.P., M.R.C.S., has been appointed Surgeon to the Chelsea, Brompton, and Belgrave Dispensary.

MARSHALL, WILLIAM, M.D.St.And., L.F.P.S.Glas., has been re-elected Physician to the Dumfries and Galloway Royal Infirmary.

MITCHELL, ANDREW, M.B., C.M.Aber., has been reappointed Medical Officer by the Parochial Board of New Deer, Aberdeenshire.

MOXHAM, M. CAMPLIN, M.R.C.S., L.R.C.P., L.S.A., has been appointed House-Surgeon to the Central London Ophthalmic Hospital, vice G. Barker, M.R.C.S., resigned.

PERRY, E. COOPER, M.A., M.B.Cantab., has been appointed Assistant Physician to Guy's Hospital.

PITT, G. M., M.A., M.D.Cantab., M.R.C.P.Lond., has been appointed Assistant Physician to Guy's Hospital.

SCOTT, WILLIAM, M.D.Ed., L.R.C.S.Ed., has been reappointed Consulting Surgeon to the Dumfries and Galloway Royal Infirmary.

SMYTH, JAMES CAMAC, L.R.C.S., L.R.C.P., has been appointed Medical Officer to the County Antrim Prison; also Medical Officer to the Brookfield and Edenderry Spinning Mills and Factories, vice John Moore, M.D., deceased.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE LATE DR. WILSON FOX.

WE are asked to state that Mrs. Wilson Fox feels deep gratitude to a large number of members of the medical profession for kind letters of sympathy and condolence which have been addressed to her and other members of the family. She begs the writers, at the present time, to accept her thanks, and to understand that owing to the largeness of this expression of sympathy it has been, as yet, impossible to send individual replies. We may take this opportunity of supplying an omission inadvertently made last week in our obituary notice of Dr. Wilson Fox—viz., that he held the office of Physician in Ordinary to the Queen. An obvious typographical error occurred also in the date given as that at which he took his M.D. degree, 1855 being misprinted 1885.

No. 420.—Our correspondent wishes to apply to the regulations generally an answer which was given to a question on one specific point. This is, of course, inadmissible.

Observer has apparently omitted to notice our comments on the case, which appeared in our impression of the 7th inst.

Viator has not enclosed his card.

COCAINE IN AURAL SURGERY.

To the Editors of THE LANCET.

SIRS,—Not having seen mentioned the use of cocaine during the removal of polypi from the middle ear, I should like to state that I have found the operation a painless one after having applied two or three times a ten-per-cent. solution of the hydrochlorate on a probe tipped with cotton wool, the cocaine also acting as a slight hæmostatic—an effect similar to which I have noticed when applied to bleeding and irritable ulcers of lip prior to cauterisation.

I am, Sirs, yours faithfully,

Burntisland, May 16th, 1887. C. BATTEN GRACIE.

UVULATOMES.

To the Editors of THE LANCET.

SIRS,—My attention has just been called to a uvulatome, described in THE LANCET of May 7th, by Dr. Greville MacDonald. Permit me to say that Mathim of this city made for me an identical instrument in the year 1855, and that a plate of it, with a slight modification, has appeared in his annual catalogues ever since that date.

I am, Sirs, very respectfully yours,

Paris, May 17th, 1887. EDWARD WARREN-BEY, M.D., C.M., LL.D.

THE MOXON MEMORIAL FUND.

PRESIDENT: Sir William Jenner, Bart., M.D., K.C.B., F.R.S. As it is desired soon to close the subscription list, any persons desirous of contributing should forward their subscriptions without delay to the honorary treasurer, E. Clement Lucas, B.S., F.R.C.S., 18, Finsbury-square, E.C., by whom they will be acknowledged. Cheques should be crossed "City Bank."

Sixth List.

Subscriptions announced	£594	0	6	R. Innes Nisbett, Esq.	£1	1	0
F. Wallace, Esq.	3	3	0	W. R. Grove, M.D.	1	1	0
T. A. Titley, Esq.	2	5	0	J. Poland, F.R.C.S.	1	1	0
W. G. H. Hunt, Esq.	2	2	0	G. F. Farr, Esq.	1	1	0
F. Frank, M.D.	2	2	0	J. C. Steele, M.D.	1	1	0
Sir Henry Acland	2	2	0	J. Ewart, Esq.	1	1	0
R. F. Stephens, Esq.	2	2	0	H. Blatherwick, Esq.	1	1	0
A. L. Galabin, M.D.	2	2	0	F. S. Pilkington, Esq.	0	10	6
H. W. Strahan	2	2	0	F. A. Hine, Esq.	0	10	6
A. G. Osborn, Esq.	1	1	0				

Erratum.—The name of *Dr. W. R. Dakin* appeared in the last list as "M. C. Dalton."

Doubtful.—Either course is permissible, though the first-mentioned is perhaps the more advisable.

Mr. R. Thistlethwayte.—The first-named is practically an honours degree.

Dr. Whitelaw Bourne.—Yes, shortly.

SUICIDE OF SCORPIONS.

To the Editors of THE LANCET.

SIRS,—If you will do me the favour of looking into vol. xxi., p. 325, of *Nature*, you will, I think, find that Dr. Bourne's experiments on these creatures have been long since substantially discounted by me. I did not, however, base any memoir or other essay on these. I did not, indeed, think the game worth the candle; and my object in making them at all was to test Goldsmith's assertion that if "a scorpion is placed in the midst of a circle of burning charcoal ..... it stings itself on the back of the head, and in this manner the undaunted suicide instantly expires." It does nothing of the kind. As to Byron's more glowing description or episode—

> "The mind that broods o'er guilty woes
> Is like the scorpion girt by fire.
> * * * * * *
> One, and sole relief she knows—
> The sting she nourished for her foes,
> Whose venom never yet was vain,
> Gives but one pang and cures all pain,
> And darts into her desperate brain;"

and so, it would appear, shuffles off the mortal coil, along with all its throes and woes, &c.—again I say it does nothing of the kind. On the contrary, and as the outcome of hundreds of these experiments—experiments that were carried out by me in the presence or with the co-operation of a score or more of still living officers, not only at the Jannairi ball practice ground at Cawnpore, but also in sundry hill and cholera camps elsewhere in India—I came to the conclusion that this belief or superstition was entirely erroneous. I came to the further conclusion that its poison was all but inert, not only on itself, but also on small birds, bees, &c.; and as to its own individual behaviour in presence of fire, it was both stupid and cowardly. It either slunk away into any corner it could either make or find, or, moving about aimlessly within this circle, it either perished in the same or died without making any sign inside it.

I am, Sirs, your obedient servant,

Auriol-road, W., May 16th, 1887. W. CURRAN.

THE SHOVEL SHOE.

To the Editors of THE LANCET.

SIRS,—You and some of your readers may recognise the signature at the foot of this letter as that of one who has a "craze for cripples," or, to put it another way, of one who has busied himself in Italy and England for the last eight years with the provision of Beaufort arms and legs for the crippled poor. Those who know the Beaufort foot will recollect that to save expense the inventor got rid of an ankle joint by adopting a foot with a curved sole. This item of the invention dates back some forty years—so I learn from the Count de Beaufort. The other day, while driving in Rome, I saw a mule yoked to a cart, which, having an ankylosed pastern joint, was shod with a curved iron shoe. I was so much struck with the arrangement that I made an appointment with the carter to bring his cart and mule to pay me a visit. I made sketches, of which I send you copies. I do not think such a system can have ever prevailed in England; for a horse with a stiff pastern joint would surely be shod. The application of the curved sole to the mule is very imperfect; for the wear on the specimen shoveł shoe ("ferro a paletta") before me appears only from the point to a little short of mid-way of the curve. The result was a deplorable limp. After due inquiry, I find that this system of shoeing is traditional, and that the name of its inventor must remain for ever unknown. Similar drawings to those I send you I submitted to the Count de Beaufort. His only remark was: "How strange that this plan should have been tried on animals so long before it was tried on men, though that dates forty years back."

I am, Sirs, yours faithfully,

HENRY H. MAXWELL,

Rome, May 9th, 1887. Captain R.A.M.C. (Militia).

QUALIFICATIONS FOR PRACTICE IN THE CHANNEL ISLANDS.

ACCORDING to the last law—that of 1875—an English diploma will entitle its possessor to practise in the Channel Islands; but he must previously obtain the permission of the Royal Court.

Dr. James Weaver.—We regret that we are unable to afford space for the series of cases promised, and advise our correspondent to submit his facts and propositions to the judgment of a medical society, where they might be adequately discussed.

Mr. Freeman (Bath).—The paper will appear shortly.

"MEDICAL ATTENDANCE ON THE POOR."

To the Editors of THE LANCET.

SIRS,—I have read with some amusement Dr. Alderson's letter on the above subject, in your issue of the 30th ult. He must indeed be a fortunate general practitioner if he can afford to attend persons with an income of £312 a year as "club" patients, an income which, according to Dr. Thurstan's letter, exceeds that of the average medical man? It is a little remarkable that men who have made their fortunes by consulting practice, men who charge fees from one to two hundred guineas and upwards, should begrudge the general practitioner a poor half-a-crown fee. So anxious do some appear that the British public should not be over-charged, that I believe they would have all medical attendance (except that done by themselves) given *con amore*. Perhaps they will extend their philanthropy still further, and suggest some means of assistance to the new class of paupers they are trying to raise from the general practitioners and their families. Some of the people are, however, beginning to find that the cheapest is not always the best, even in medical matters. The good labourer is always worthy of his hire. And they cannot have their cases carefully gone into by well-qualified men for a fee ranging from twopence to sixpence. I know several cheap surgeries and dispensaries where the patients are habitually attended by men who have never seen the inside of a medical school. There are many dispensaries that have no medical man's name on the door. These are mostly kept by unqualified practitioners, protected by some of our brethren. This is a public matter that should be inquired into by Government, but the much-abused Apothecaries' Hall appears to be the only protector of professional interests and the public health. The Colleges and Universities should prohibit their graduates from establishing branches that they cannot personally superintend.

I am, Sirs, yours obediently,

May 12th, 1887. F. T. S.

Medical Staff.—We do not agree with our correspondent. In the two instances quoted, the military officer was wrong, and if the cases had been brought to the notice of the authorities we have no doubt he would have been properly instructed on the subject—probably in the shape of a reprimand.

Mr. Edwards.—Too late for this week.

THE LATE DR. WILSON FOX.

To the Editors of THE LANCET.

SIRS,—I think your readers would like to know that the late Dr. Wilson Fox was in the habit of placing his beautiful house at Eydal at the disposal of the Bishop of Bedford, for the use of the invalided East-end clergy and their families during the summer months. The liberality, kindness, and delicacy with which this was done will be understood by all who knew him. One might not speak of this while he was living; but now that he is gone, it is impossible to withhold this fact from the record of his goodness.

I am, Sirs, yours faithfully,

Mile-end, E., May, 1887. ONE OF THE CLERGY.

Alpha.—We regret that our correspondent should have received the impression to which he refers in his private note. He is entirely wrong on that point, and we cannot but think that a careful perusal of the various articles in THE LANCET bearing on the interests of the service would convince him of the warm interest we take in it, though we happen to differ from him in some points.

Mr. B. Walker (Spondon).—Yes.

EXCISION OF CHANCRES.

To the Editors of THE LANCET.

SIRS,—I see in your journal of Feb. 19th a notice that Dr. Andronicos claims to have entirely eradicated the syphilitic virus by excising the primary sore. I tried the plan myself in November; but besides excising I carefully cauterised the wound with strong nitric acid. I saw the patient some three months afterwards, and could find no trace of syphilis on him.

I am, Sirs, yours faithfully,

Nagasaki, Japan. C. ARTHUR ARNOLD, M.B., C.M.

BROWN DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Will you kindly allow me to acknowledge the receipt of the following additional subscriptions towards the above fund? Amount already acknowledged, £16 15s.; Sidney Jones, Esq., £1 1s.; Dr. J. Macwhirter Dunbar, £1 1s.; J. Quinton Bown, Esq., 10s. 6d.

I am, Sir, faithfully yours,

G. STANLEY MURRAY, M.D.

23, Upper Richmond-road, Putney, May 17th, 1887.

TREATMENT OF MASTITIS.

To the Editors of THE LANCET.

SIRS,—Permit me through your pages to call attention to a method of treating this affection, first brought before the notice of the profession about nine years ago by a practitioner in the south of England, whose name, I regret to say, I cannot recollect—a method which, if I may judge by the fact that no reference has been made to it in the various articles which have appeared from time to time in your journal, has not received that attention which my own experience leads me to consider it deserves. The gentleman to whom I refer treated this disease first by a ten-grain dose of quinine, and then by a two-minim dose of tincture of aconite, every ten minutes for the space of four hours, continuing the same dose afterwards once every four hours. At the same time extract of belladonna liquefied by glycerine in the proportion of one part to eight was applied locally. Since that time I have always used this method of treatment, latterly without the quinine, and in almost every instance have found it cut short the affection at once, nipping in the bud this painful and troublesome disease. I have found it far more reliable, and at the same time less troublesome, than any other mode of treatment, and I have not seen any alarming consequences from the action of the aconite on the heart. In one case only did the pulse become slow and intermittent, and in this case, a delicate woman, strict confinement to the recumbent posture was maintained for a day or two, and she made a good recovery. All my other cases have led me to consider that little, if any, danger need be apprehended where the heart is sound and there is much pyrexia. Lately I have given the tincture of aconite only once in a quarter of an hour with good results.

I am, Sirs, yours truly,

Rotherham, May 11th, 1887. WM. OXLEY.

COMPLETE SELF-ENUCLEATION OF AN EYEBALL.

To the Editors of THE LANCET.

SIRS,—As reported in your last issue, I recently brought before the Ophthalmological Society the details of a case of self-mutilation in which a woman completely enucleated one of her eyes. If any members of the profession have had any cases under their observation, and will kindly favour me with particulars, I shall be greatly obliged to them.

I am, Sirs, yours faithfully,

15, Stratford-place, W., May 17th, 1887. J. GROSVENOR MACKINLAY.

Dr. A. Hutchison (Loughborough).—Our correspondent can refer with advantage to "Ribot on Heredity," and to Galton's work, "English Men of Science;" also to the chapters on Heredity in the "Dictionnaire des Sciences Médicales." We do not know of any detailed account of the Stuart family.

Mr. J. A. Jones (Tir Caradoc).—The matter shall have consideration.

Dr. H. Leffmann (Philadelphia) is thanked.

Mr. C. J. Bond (Leicester).—Yes.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Hale White, London; Mr. C. Heath; Dr. Fothergill, London; Mr. Bennett May, Birmingham; Mr. W. Curran, London; General Maxwell; Mr. J. Clinical Notes on STERILITY.

By GRAILY HEWITT, M.D., F.R.C.P.,
PROFESSOR OF MIDWIFERY AND DISEASES OF WOMEN, UNIVERSITY COLLEGE; OBSTETRIC PHYSICIAN TO THE HOSPITAL.

ALTHOUGH it cannot be denied that in a certain number of cases sterility in the woman is due to what may be termed general causes or conditions in other ways unfavourable to the occurrence of conception, yet what is known on the subject of the cure of sterility is consistent with the idea that interference with patency of the passage of the uterine canal constitutes the most common cause of sterility. Hence interest chiefly attaches to the question, What are the abnormal conditions of the cervix uteri and its lower and upper inlet which may interfere with the patency necessary for insemination? Abnormal conditions in the ovaries, in the Fallopian tubes, in the body of the uterus, may cause sterility, but these irregularities are less open to recognition, whereas the cervical canal readily admits of examination. The success which has followed various methods of dilatation, incision, and enlargement of the passage of the cervical canal with the view of curing sterility, amply justifies the amount of attention which has been directed to this part of the uterus in the endeavour to deal with the evil.

One of the latest writers on sterility, Dr. Matthews Duncan, admits the frequent success of treatment of dysmenorrhœa by enlargement of the cervical passage, and the occasional success of the same treatment in curing sterility. But he denies that the enlargement of the passage is the cause of the cure, because, as he contends, the passage is already open. The mechanical dilatation seems "in some mysterious way" to exert a generally beneficial influence under such circumstances. He dwells, however, on the presence of rigidity of the cervix as an important factor in these cases. That dilatation under such circumstances is removal of a mechanical obstruction it seems reasonable to suppose, but Dr. Matthews Duncan denies this. He is in favour of the view, which was, I believe, first suggested by Coste, that the orgasm of coitus tends to produce a patent condition of the cervix. This appears to be the fact, but it follows also that a rigid condition of the cervix would be likely to interfere with this increase in the cervical patency, and would therefore constitute an obstruction.

Although the influence of flexion of the uterus in producing obstruction of the uterine canal has been vehemently denied, clinical facts appear to me to indicate that obstruction may be and is frequently thereby brought about. So far as the question of sterility is concerned, the facts, I believe, are as follows:—Obstruction of the cervical canal at and near the internal os uteri is liable to be produced by marked flexion of the uterus. Under these circumstances the uterine canal becomes flattened out, and the anterior and posterior walls brought into apposition. Such coaptation of the opposite walls of the uterine canal, and affecting the canal for upwards of half an inch according to the acuteness of the bend, more or less, will constitute an obstruction to the occurrence of insemination. The condition of the tissues of the cervix and of the walls of the canal, in fact—will also materially affect the patency of the canal, for if the uterus has for a long time been in a state of flexion, and has become hardened and consolidated in that shape, the obstruction to insemination will be likely to be greater than in a case where the flexion is of recent origin. There will be "rigidity" of the cervix also to a greater or less degree. When the uterus is found doubled upon itself and the greater part of the canal, constituting a curve of an elliptical shape, which is the condition in many cases of acute uterine flexion, there will arise a tendency to coaptation and virtual closure of the canal. This does not necessarily prevent passage of the sound into the uterus, whence it has been argued, but most erroneously as I believe, that there is no obstruction present. In a sense the canal is open, no doubt, and probably in the early stages of the case, the uterus retaining its flexibility and no "rigidity" of the tissues of the cervix present, no obstructive effects may arise, because the organ is still capable of straightening itself during the orgasm produced by coitus. The occurrence of straightening separates the walls of the tube, and for the time obstruction is removed. When later on the uterus is both rigid and flexed, as frequently happens in long-standing cases of flexions, the case is different, and a practically impermeable condition of the cervical canal, at and near the internal os, supervenes. There are, no doubt, many cases in which the uterus is flexed, and the canal more or less decidedly curved, but in which, nevertheless, pregnancy occurs. The presence of flexion of the uterus does not necessarily imply persistent interference with the patency of the canal. But when the degree of flexion is pronounced and the uterus has become hardened and fixed in that particular shape, then in a considerable number of cases the patency of the canal may be so affected that conception is prevented from occurring. Thus the degree of flexion is probably not so important a factor as its irreducibility. If the uterus is firmly set in its flexed shape, the coaptation of the anterior and posterior walls of the canal, which is liable to be present at and near the internal os uteri in such cases, persists, and an obstacle is thus interposed such as may effectively prevent insemination. The induration of the tissues of the cervix, due to sclerotic contraction, which is liable to be observed in long-standing cases, renders the straightening of the canal more and more difficult. If my interpretation of the phenomena observed in such cases is correct, the cure of sterility, so far as the cervix and os uteri are concerned, will be found to be necessarily associated with measures calculated to remove the source of difficulty, and to thus restore the patency of the uterine canal. Numerous records published prove that conception is far more likely to occur when steps have been taken to improve the state of the uterus in this particular than when these steps have been omitted. Forcible dilatation of the cervix by bougies is one of the methods by which this object can be secured, and is more or less applicable in different cases.

It is disputed by some authorities that mere straightening of the canal is of assistance in regard to improving its permeability. This idea is certainly not borne out by my experience, nor is it supported by the facts adduced by those who rely on dilatation alone for the cure of sterility. When the cervix is dilated it is also straightened. Unquestionably, the patency is improved by dilatation, but inasmuch as the procedure in question has the effect also of straightening the canal, it may be doubted whether the benefit is derivable from the dilatation or from the straightening. The simplest case illustrative of the bearing of this question is that in which the uterus is markedly retroflexed. Here the patency of the canal is interfered with, as I suppose, in consequence of the compression of the cervical canal in the antero-posterior direction, whereby it is flattened and its calibre diminished so long as the bending of the organ remains. Now it is possible, as clinical facts show, that the sterility arising in such a case may be cured either by raising the fundus uteri, and thus doing away with the flexion, or by dilating the uterine canal. But if the mere elevation of the fundus is effectual, what becomes of the argument for the necessity for forced dilatation? It is, in view of this fact, more reasonable to attribute the success of the dilatation to the straightening of the uterus, or at least it is very unreasonable to deny the efficacy of the dilatation *qua* the straightening which is its inevitable concomitant. I do not intend to dispute the efficacy of dilatation, but to show the incorrectness of deductions which have been drawn from that success in regard to the remedial power of straightening *per se*, and the matter seems important in estimating and interpreting aright the results of experience of the two methods of dealing with sterility which have been above alluded to.

In illustration of the foregoing remarks I propose to subjoin the following series of cases, which came under notice during a period extending over eight years, and ending about eight years ago. They were not all treated for sterility, but in most of them the absence of procreation was a noteworthy part of the case. In some the sterility was what may be termed "primary"; in others the sterility was "secondary," there having been one or more children born, followed by a cessation of child-bearing. It will be noted that the method of treatment adopted in these cases was limited, except in about three of them, to straightening of

Digitized by Google

the canal and maintenance of the proper position of the uterus by a pessary, so that the cases offer evidence of a favourable character in regard to the beneficial influence of this method of dealing with such cases.

CASE 1.—Mrs. J——, aged about twenty-three, from the west of England, married one year and a half, has had dysmenorrhœa for nine years, which came on first after a day's hunting. Latterly the pain continued the whole of the period. Walking produces exhaustion. Uterus severely retroflexed. Treatment by a combined Hodge and stem pessary. Cure of the displacement, and pregnancy followed with a satisfactory result in the birth of a mature child.

CASE 2.—Mrs. ——, aged nineteen, was sent to me from Yorkshire. She had been married fourteen months. Menstruation profuse, spread over too long a period, lately painful, accompanied with sickness. A pessary has been tried, but found not to answer. It appears that four years before marriage the patient had an attack of scarlet fever, as the result of which she did not walk for one year, being so weak, and then was obliged to use crutches. Has had occasional hysterical attacks since the scarlet fever. The os uteri was found soft, and it was thought just possible that she was pregnant. After waiting a little, however, this proved not to be the case. Uterus found retroflexed. A modified Hodge pessary was adjusted. The pessary was worn for a considerable time. I subsequently learned that the patient became pregnant two years after I had seen her, and delivery took place at term.

CASE 3.—Mrs. ——, aged twenty-eight, the wife of an officer in the army, had been married four years; no pregnancy. She first felt pain in the groin four years ago, with dragging pain in back and in legs, which prevented her standing or walking long at a time. Menstruation regular, a little painful; leucorrhœa. Complained also of a burning heat in the head. The uterus is severely retroflexed, the cavity half an inch too long. Reduced easily, but at once returns to flexed state on withdrawing sound. Uterus is also very low in pelvis. Was formerly accustomed to walk four or five miles at a time, even during menstrual periods. The patient underwent treatment, consisting of the use of a pessary, aided by rest and occasional use of sound. The restoration of the uterus to its proper shape occupied some time. One year and eight months after first consultation she became pregnant, and was delivered naturally at full term.

CASE 4.—Mrs. M. G——, aged twenty-two. Married two years. Has been abroad in a warm climate, and had a miscarriage (probably) just after marriage. Had dysmenorrhœa much since marriage. Exertion and walking very productive of discomfort. Was treated by a pessary before marriage (ring pessary). Has also worn it lately, but it is found to slip. A Hodge-shaped pessary was accordingly introduced, the uterus being found retroflexed. She went away and had a child two years and three months after the commencement of treatment. Seen again two years after birth of the child, it was found that she was wearing a ring pessary. The uterus had again become retroflexed, and was now large and heavy.

CASE 5.—Mrs. L——, married one year. Had an abortion eight months ago from horse riding. Uterus retroflexed acutely. Treated by a Hodge-shaped pessary. Pregnancy occurred about a year later; result satisfactory.

CASE 6.—Mrs. C——, aged thirty-two. Had four children, last one year ago. Uterus retroflexed. Patient a great invalid. Treated by Hodge-shaped pessary, rest, &c. The pessary was worn for a considerable time (nearly three years), at the end of which she was found to be four months pregnant and the pessary was removed. Result good.

CASE 7.—Mrs. ——, aged twenty-two, was sent to me from the west of England. She had been married early, and had two children, the last four years ago. Since that time she had suffered from "ulceration." Had formerly a specific affection of the milder type. Suffers from some degree of prolapsus, bearing down, &c. Menstruation occurs every ten or fourteen days; is scanty and painful. Walking causes great pain. Suffers from nausea. Uterus is retroflexed, easily replaced. A pessary on the Hodge principle adopted. Four months later she was again seen; uterus now in good position, although she has been without the instrument for the last three weeks. It was thought best for her to have a pessary a little longer. This patient had another child shortly after the above treatment.

CASE 8.—Mrs. ——, aged twenty-eight, the wife of an officer, a lady from the north of England. Had had two children, the last four years before. She had been ill for two years, suffering from prolapsus. Previously to that time had much to do, and exerted herself too much. Uterus in a state of acute retroflexion, lying very low in pelvis. She was in a state of great prostration, excessively weak and thin, and a complete invalid. The uterus was much hypertrophied. The treatment consisted in careful repositions of the uterus and adjustment of a pessary, with assiduous attention to dietary &c. At first a rather large pessary was required to keep the fundus from descending posteriorly, and it was some time before the patient seemed to make progress, though the discomfort ceased quickly. After about three months she was able to get about, but continued to wear the pessary much longer. Four years afterwards this patient had another child; she had worn the pessary almost continuously, it having been found impossible to dispense with it.

CASE 9.—Mrs. ——, aged thirty-three, sent to me from Norwood. She had had five children, the last five years before; and since that two miscarriages, the last six months ago. Uterus found to be much thickened, and large universally. Much retroflexed; reduction not difficult; returns to flexed state at once. There is not much pain felt in using the sound. The patient was treated by rest and the use of a pessary of modified Hodge shape, but covered with india-rubber, and the pessary rather thick (ten millimetres). She continued to wear this pessary, feeling quite well, and four years later came to me stating that she was then pregnant. I found her still wearing the pessary, and removed it. She was nearly five months pregnant.

CASE 10.—Mrs. ——, aged twenty-three. Has had one child, about two years ago. Suffers from cough and troublesome uterine symptoms. Uterus retroflexed. A Hodge pessary was applied, and the patient had a second child later on.

CASE 11.—Mrs. ——, aged thirty-three, married nearly two years. Took much walking exercise after marriage. Suffers from severe menorrhagia. Is now unfit for exertion and generally ill. Uterus found to be acutely anteflexed, half an inch too long, and fundus enlarged. At first it was considered to be a case of fibroid growth in the anterior uterine wall, and the uterus was dilated in order to gain access to this. But it resolved itself into a case of acute anteflexion. Pregnancy resulted shortly afterwards, and ended favourably.

CASE 12. Mrs. T——, aged twenty, married seven months when first seen. Suffers much, and is very weak and incompetent for exertion. Uterus much anteflexed. Amenorrhœa. Patient treated for some time by general measures; later on treated by a stem pessary, and subsequently by a cradle pessary. Pregnancy occurred first three years after marriage. Later on the symptoms recurred, and the pessary was again employed, with result of a second pregnancy and this sequence of events was again observed. The uterus was in this case apparently thin walled, and the organ became flexed. It is noteworthy that in this case, at a still later period, the patient again applied for relief, and it was then found that the uterus had become retroflexed, and a Hodge pessary was required to place her in a condition of comfort.

CASE 13.—Mrs. ——, aged twenty-seven, married six months. Suffers from menorrhagia and dysmenorrhœa, also pain after walking. Uterus acutely anteflexed. Treated by cradle pessary. Eleven months after first seen was found to be three months pregnant; still wearing pessary, which was then removed.

CASE 14.—Mrs. ——, aged twenty-seven, married seven years. Suffers from dysmenorrhœa and a very sensitive condition of the uterus. Acute anteflexion. Treated by a cradle pessary and use of sound. Treatment continued for about six months. Pregnancy occurred one year and a half later.

CASE 15.—Mrs. ——, from the United States. Had been married for six years, and had been under treatment for uterine disorder for four years. Principal complaint, dysmenorrhœa, which existed from first menstruation. Lately an operation had been suggested. I found the uterus acutely anteflexed, but the flexion was very high up, and the top of the fundus seemed to be enlarged. Entrance of sound difficult at the seat of the flexion. The patient objected to any operation, and the use of a cradle pessary was advised. By means of a cradle with a rather high bridge the flexion was controlled, and the patient made much easier. She continued to use the pessary (removing it at night) for a considerable time, and I saw her occasionally at intervals of two or three years. The passage of the sound finally

Digitized by Google

became easier, and nine years after I first saw her, and after fourteen or fifteen years of married life, pregnancy for the first time occurred. The occurrence of pregnancy after so long a continuance of the sterility is especially noteworthy.

CASE 16.—Mrs. ——, aged twenty-six, a lady who had been married nine years, had been under treatment for some time when she consulted me. There had been no pregnancy. Suffering consisted chiefly of a continual severe backache. I found the uterus considerably swollen and much anteflexed. The fundus uteri was very low down in front, and it was exceedingly difficult to raise it from this position. Inquiry appeared to trace this position to a very severe fall in early childhood. The uterus was gradually elevated, and a cradle pessary employed. This occupied much time, and afterwards the uterine canal was periodically dilated by a two-bladed dilator. These measures were finally successful, and pregnancy occurred, followed by a natural delivery three years after I first saw the patient.

CASE 17.—Mrs. ——, aged forty-two. Has been married eleven years; no pregnancy. Menstrual periods too often, and frightfully painful almost always. The uterus appears to be enlarged anteriorly, as if by presence of a tumour. The sound cannot be introduced more than a short distance. Further examination proved that the case was one of severe anteflexion, and the sound was fully introduced. The cervical canal was then dilated from time to time, and a cradle pessary was employed. Nine months afterwards this patient became pregnant, and was seen by me when eight months and a half advanced.

CASE 18.—Mrs. ——, aged twenty-nine, was sent to me from abroad. Had been married ten years and had several miscarriages, the last two years and a half ago. Menstruation very irregular. Has had much travelling of a fatiguing nature. The uterus is markedly anteflexed; the canal very sensitive at internal os. Treated by cradle pessary, with great relief from uterine symptoms. This was removed after some months, but resumed after a long interval. Finally she became pregnant while wearing the pessary, went to her full time, and was delivered of a living child five years after first consulting me and after sixteen years of married life.

CASE 19.—Mrs. ——, aged thirty-two, married seven months. Seen in consultation with my friend, Dr. Murray of Newcastle-on-Tyne. Has suffered from backache severely for some years. Leads a very active life. Menstruation intermittent. Uterus anteflexed, large, congested; the bend of the uterus is high up; sound pretty readily introduced. The patient wore a cradle pessary and the uterine canal was dilated by Dr. Murray. Pregnancy occurred not long afterwards.

CASE 20. Mrs. S——, aged thirty-five, seen with Dr. Burton. Married six years; no pregnancy. Has had treatment for uterine displacement for one year. Suffers from pain and leucorrhœa. Uterus found anteflexed, large; tissues of uterus soft; sound enters pretty easily. Was treated by a cradle pessary. The patient became pregnant, and had a miscarriage five months afterwards. The pessary was discontinued for a time and then again employed. A second pregnancy followed, and there was a threatening of a miscarriage, but this went off and the patient had a living child at full term.

CASE 21.—Mrs. T——, aged thirty-four. Has been married four years. It is thought there was a miscarriage last year. For the last five months she had frequent micturition. Uterus much anteverted, pressing on the bladder. She was treated by a cradle pessary, the uterus being large and heavy. Pregnancy occurred while wearing the pessary one year and a half afterwards, and, I believe, ended satisfactorily.

CASE 22.—Mrs. L——, aged twenty-seven. Had a miscarriage eleven months ago, due to over-exertion. Uterus low down, anteflexed to left side. Os uteri soft; sound difficult to pass. Treated by a cradle pessary. Six months afterwards the patient proved to be pregnant, and with, I believe, a satisfactory termination. The pessary was worn up to about the time of quickening.

CASE 23.—Mrs. ——, aged twenty-six. Has had one child three years ago, since which she has suffered much from backache. Menstruation irregular and painful. Uterus much anteflexed. Wore a pessary for some time. One year later, reported to be pregnant.

CASE 24.—Mrs. ——, aged twenty-seven. Had had two children, the last two years previously. There had been one miscarriage also previous to first child. Some little time ago she strained herself in catching a box, and is now not able to walk; she suffers also from hysterical attacks after exertion. Uterus anteflexed; the anterior lip much elongated. Use of sound a little difficult. A cradle pessary was employed, which enabled her to walk easily. Pregnancy occurred again in three months.

CASE 25.—Mrs. ——, aged twenty-five, the mother of one child nearly three years old. States that she walked too much after her confinement, and has not been well since. Suffers from pain on rising, also from nausea. The periods are long apart. She can walk a little in the afternoon. Uterus acutely anteflexed. Sound very difficult to introduce. Treated at first by an air-ball pessary, then by a cradle pessary. Six months later pains relieved. The pessary continued to be worn for some time, altered in shape occasionally, as much difficulty was encountered in maintaining proper position of the uterus. Two years and a half after commencement of the treatment pregnancy again occurred, the patient having worn a pessary up to that time.

CASE 26.—Mrs. ——, aged twenty-eight. Has had three children, last two years and a half ago. Had a miscarriage eight months ago. Suffering from great depression and hysterical symptoms. Uterus large and much anteverted; os uteri far back. Treated with a cradle pessary for six months. Pregnancy followed shortly afterwards.

CASE 27.—Mrs. ——, aged about thirty-two, the wife of a medical man. Has had two children, the first twelve years and the last three years ago. Suffers much from dysmenorrhœa, menorrhagia, and leucorrhœa. Uterus anteflexed and to the right side; os uteri much congested. General remedies were at first tried, without result. A cradle pessary was then employed. Great relief obtained. Patient had another child soon afterwards. Subsequently the displacement recurred and became very troublesome. The pessary was again successfully employed.

CASE 28.—Mrs. ——, aged thirty-one. Had two children, and two miscarriages since. Menstruation profuse. Has a constant sensation of bearing down. Five months ago she was confined to her bed for a week with pains so severe as to resemble labour pains. Much leucorrhœa and sickness during the last three months, especially in the morning. Feeling of numbness in the lower part of the body. Uterus much anteflexed; it is easy to straighten it, but the flexion immediately recurs. A cradle pessary was adjusted. Six months later she became pregnant. She was advised to be very careful, and the result was good. I saw this patient again five years afterwards. She had had another miscarriage one year after the third child was born, from which I infer that the uterus afterwards resumed its anteflexed shape.

CASE 29.—Mrs. ——, aged about thirty. Has had two children. A year ago had a miscarriage at three months. The ovum, or a part of it, was retained for a month, and puerperal fever occurred. This was in India. Now suffers from pain in the right side, faintings, and general illness. Uterus anteflexed and soft to the touch. A cradle pessary was employed. The patient recovered, and had another child later on.

CASE 30.—Mrs. ——, aged thirty. Had two children, last two years ago; also miscarriage a year ago. Since that time not so well. Has had almost continued loss during last four months. Periods painful. Has had leucorrhœa. Walking very painful. Uterus anteflexed; anterior lip elongated; os crescentic in shape; Nabothian follicles enlarged. A cradle pessary was employed, together with other general treatment. Patient pregnant one year later, the pessary having been removed six months. Now suffering from sickness owing to the pregnancy. Cradle pessary again used to relieve the sickness.

In order to estimate the bearing of these cases on the question of the value of treatment in cases of sterility, the cases must be classified according as they were cases of primary sterility or secondary sterility. Regarding primary sterility, a further division is required into (*a*) cases where no pregnancy had occurred, and (*b*) cases in which pregnancy had occurred but ended in abortion. Respecting the retroflexion cases related, it will be found that three were cases of primary sterility without previous abortion, that in two the patients had had abortions, and that the remaining five were cases in which secondary sterility had existed for a number of years, and was relieved by curing or ameliorating the flexion, which was the assigned cause of the secondary sterility. Regarding the anteflexion cases, nine were instances of primary sterility without abortions, cured by treatment; three were cases in which the patient had been pregnant before, but followed by abortion; and eight

Digitized by Google

were instances of secondary sterility, relieved by straightening or partially dilating the cervical canal.

Some of the cases mentioned were instances of primary sterility of very long standing. Thus in Case 3 the duration of the sterility was four years, due to an obstinate retroflexion. In Case 8 there was secondary sterility from retroflexion of four years' standing. In Case 9 secondary sterility of six years from a similar cause. Of the anteflexions, in Case 14 there was primary sterility of eight years and a half's duration; in Case 15—a remarkable one—the sterility (primary) was of upwards of fourteen years' duration; in Case 16 the patient had been married without issue for twelve years; in Case 17 the patient first became a mother at the age of forty-two, after a married life of eleven years' duration; in Case 18 the patient had had several miscarriages and been married sixteen years when she became a mother; in Case 20 the sterility (primary) was of six and in Case 21 of four years' duration; in Case 25 secondary sterility was of three years' duration when treatment commenced.

It will be observed that the occurrence of abortion is noted in some of the cases above related. Sterility is not seldom witnessed in women who are liable to abortions. The fact is one of great importance. Some women are apt enough to conceive, but the pregnancy ends in abortion, and this may occur repeatedly. It is certain that in many such cases the abortion is due to distortion of the uterus, which interferes with the proper expansion of the organ as the ovum grows and expands within it. Abortions may occur primarily, but more commonly it is observed that the subjects of them have had one or more children, and that there is established subsequently a liability to abortion. These latter are cases in which the uterus has become distorted after parturition and has settled down into a confirmed state of flexion, which has not been sufficiently severe to prevent conception, but sufficient to prevent healthy growth of the ovum. Hence, arises secondary sterility. In these latter cases the cure of the sterility by treatment of the flexion is an important argument in favour of the view that the confirmed severe flexion is the cause of the liability to abortion and associated sterility.

The principle of treatment which was adopted in dealing with the above cases was to improve the patency of the cervical canal by straightening it, and the method of procuring this increase of patency, which was most particularly and uniformly carried out, was the elevation of the fundus by employment of a suitable pessary. This latter procedure was the sole treatment carried out in several of the cases, but in some of them other methods were adopted. A stem pessary was used in two of the cases mentioned; in several of them the uterine sound was used as an assistance to the pessary in unfolding the flexion, and thus increasing the cervical patency. So far as these cases go, they prove that the method of treatment adopted was a successful one, and bear testimony to the efficacy of the principle of treatment carried out in these instances. In only two of the cases was dilatation of the cervix systematically carried out, and in these the dilatation was employed to a slight extent only, and not so fully as has been adopted by practitioners of repute during the last three or four years. The above cases were treated by me some years ago. Judging from more recent experience, I conclude that a more extensive adoption of the dilatation method than was carried out in the above series would be profitable, and probably the list of successful instances of the cure of sterility during the period of my practice covered by the above cases would have been longer had dilatation treatment been more largely carried out. The experience above recorded exhibits the utility of mere straightening and rectification of the positions of the uterus. Dilatation has the effect of straightening and replacing the uterus, and it offers the further advantage of getting rid, for a time at all events, of that rigidity of the cervix which is probably a great obstacle to the occurrence of pregnancy when associated, as it so frequently is, with a chronic long-standing flexion. It may be considered, possibly justly, as superior to mere straightening and maintenance of the proper position of the uterus on account of the greater rapidity with which the result is effected; but judging from cases which I have thus treated, the use of a supporting mechanism after dilatation will be found advisable if the permanent restoration of cervical patency is aimed at. For in long-standing cases the uterus may, after full dilatation, return in a few months to its abnormal flexed condition, and the patency of the cervix is liable to be again diminished.

THE BLOOD IN PERNICIOUS ANÆMIA.[1]

BY S. M. COPEMAN, M.A., M.B. CANTAB.,
DEMONSTRATOR OF PHYSIOLOGY, ST. THOMAS'S HOSPITAL; LATE SCHOLAR OF CORPUS CHRISTI COLLEGE, CAMBRIDGE.

PERNICIOUS or idiopathic anæmia has been recognised as a distinct disease since Addison first described it in 1855, but Dr. Byrom Bramwell appears to have been the first to call attention to the peculiar changes in the blood which are characteristic of this affection. Subsequent observations have in the main confirmed his descriptions, although on certain points there has been considerable difference of opinion; and accordingly when, last year, four cases of pernicious anæmia were admitted into the wards of St. Thomas's Hospital, under the care of Dr. Bristowe (curiously enough, all at about the same time), I seized the opportunity of examining the blood on a number of different occasions, with the results narrated below. The clinical history of these cases is briefly as follows:—

CASE 1.—A single woman, aged twenty-seven, who eleven years previously to admission into hospital had suffered from rheumatic fever and pericarditis. For nine months jaundice had been coming on, although the fæces remained normal in colour. The catamenia had not appeared for the same length of time. The patient was very anæmic, the skin being yellow and moist. The area of cardiac dulness was somewhat increased, and at the base the second sound was reduplicated on the left of the sternum. There was considerable pain in the right hypochondrium. The stools contained an abundance of bile, and there was no trace of bile pigment or acids in the urine. From the time of admission onwards there was an evening temperature averaging 101°, and never falling below 99·2°. After a month in the hospital there was a sudden rise to 103°, accompanied by much pain in the cardiac region, and a faint systolic murmur was found to have developed at the apex. About six weeks after admission the eyes were examined by the then house-physician, Mr. Hutton, who found optic neuritis present in both discs, which were reddened, swollen, and hazy. There were also a number of retinal hæmorrhages. The blood was pale, and coagulated rapidly; the red corpuscles numbered only about 36 per cent. of the normal quantity, and on drying a thin layer of the blood the corpuscles broke down, and crystals of hæmoglobin were formed. The patient was put on liquor arsenicalis (ten minims three times a day), and improvement commenced at once, the patient feeling better, although for a time the anæmia seemed even more marked. Before another month had elapsed the retinal hæmorrhages were becoming rapidly absorbed—those seen, four or five in number, being very ill defined and pale. The blood was also much improved. The red corpuscles (which now reached 60 per cent. of the normal number) no longer broke down, and consequently no crystals could be obtained. The patient went out three months after admission, having made steady progress towards recovery from the time that she was put upon arsenic.

CASE 2.—A leather finisher, aged thirty-two, was admitted in February, 1886, with a history of rheumatism five years previously, and frequent attacks of epistaxis for the past four years. The skin was of a pale yellowish colour; the conjunctivæ very anæmic, but apparently not jaundiced. There was a blowing systolic murmur at the apex, conducted into the axilla, and a faint double murmur at the base. Temperature 100°. On examining the eyes the optic discs were very pale; there was marked red and black stippling of the choroid but no hæmorrhages. The blood was much impoverished, the red corpuscles being present to the extent of 48 per cent. of the normal number only; they were under-sized, light-coloured, and did not run into rouleaux. A number of small highly coloured corpuscles about 2 μ in diameter were seen. Many of the larger corpuscles were of an oval or pyriform shape; they did not tend to break down, but their colouring matter was extruded in an amorphous form. At several subsequent examinations similar appearances were observed. The patient gradually improved, and was discharged on May 1st,

[1] Abstract of paper read before the Medical and Physical Society of St. Thomas's Hospital on February 17th, 1887.

Digitized by Google

but has recently been readmitted in about the same state as before.

CASE 3.—The patient was a woman, aged thirty-three, who had never been well since her confinement nine years previously. Her chief complaint was of almost continuous pain in the flanks, sometimes causing vomiting, and of shortness of breath. Though very anæmic she appeared fairly nourished; both the liver and spleen were enlarged and tender, but no enlarged glands were found. The ophthalmoscope showed marked red and black stippling of the choroid in both eyes, while in the left several patches of hæmorrhage were seen. The house-physician notes: "The blood is pale and thin; no increase of white corpuscles; the red are irregular in shape, for the most part oval or pyriform, and are smaller than normal, but there are some even larger than those found in health. In parts the colouring matter seems to have separated out from the corpuscles and to lie in red lines between them." I found the red corpuscles to be 47 per cent. of the normal number. Temperature 100·6°. Later on some œdema of the face and eyelids was noticed, followed by swelling of both legs, which, however, gradually passed off, and under the administration of arsenic the patient improved greatly in colour and appearance, the change for the better in the state of the blood also being very noticeable when she was "presented" after a stay of a couple of months in the hospital.

CASE 4.—A brewer's man, aged fifty-seven, admitted in February 1886, complaining of severe diarrhœa. He had suffered from rheumatism some time previously. He was pale, emaciated, and aged-looking, the skin being very pale and dry. No eruption. Temperature 100°. Several retinal hæmorrhages were noticed in the eyes, and on examining the blood the red corpuscles were found to number only about 40 per cent. of the normal quantity. They were very irregular in shape, and pale, although some which were very minute were dark-coloured. On drying the blood on a slide by spreading it out with a needle, the corpuscles broke down into a uniformly granular-looking mass, which, when the slides were examined the next day, seemed to have disappeared almost entirely, while in its place were seen numberless acicular crystals of hæmoglobin. In parts where a few corpuscles had persisted entire the crystals were seen to be directly derived from them, and by good fortune I was able in some instances to watch the gradual change into perfect crystals, which in these cases were larger than those derived from the broken-down material. The patient went out about a month after admission by his own desire on finding that he had not increased in weight during the previous week. He was not quite so anæmic in appearance as when admitted, and had gained considerably in strength during his stay.

In a fifth case, that of a policeman who came into the hospital some time before the others, the disease appeared to ensue on an attack of malaria, contracted in the Kentish Marshes where he had been sent to prevent prize fights. The blood presented similar appearances to those noted in Case 2, the masses of amorphous pigment being very numerous and exceedingly obvious from their large size, while the corpuscles were few in number, pale, undersized, and irregular in shape. (See Table.)

In connexion with these cases there are two points to which attention should particularly be directed, the first being the pathology of the blood, and the second the effect produced primarily on the blood, and so on the patient, by the treatment pursued.

First, as to the condition of the blood. It has long been known that the *number* of the red corpuscles in severe cases is largely diminished, the individual corpuscles being both smaller and paler than in a normal state. Dr. Bramwell observed, in addition, that their *shape* was liable to great variation, the normal change being from circular to pyriform, this doubtless being due to a diminished consistence of the stroma. He also mentioned the presence of nucleated red corpuscles, which have also been noticed by other writers. But in all probability the nucleation is only apparent, being due to the fact that the hæmoglobin has become accumulated towards one part of the cell, as a very similar appearance can be produced artificially in human blood by the action of tannic acid. The *size* of the red corpuscle is diminished often to a great extent, the diameter usually ranging between 4 μ and 7 μ, although occasionally there are seen some which exceed in diameter the largest of those found in health, the measurement in exceptional cases being even as much as 14 μ. Dr. Hermann Eichorst notes the presence of corpuscles of a very small size, not more than 3 μ in diameter, which differ from the others in that they are globular, instead of the usual biconcave form, while they are also of a much deeper red than normal. Dr. Bramwell admits the presence of these minute corpuscles, but has failed to observe their deeper colour, in connexion with which statement it is curious that I rarely failed to find them. The *number* of red corpuscles present is much reduced, the hæmocytometer showing an average of from 35 per cent. to 45 per cent. of normal. The corpuscles are also apt to change their form as noted above, becoming pyriform or spindle-shaped. When the consistence of the stroma is thus altered, the colouring matter tends to leave the corpuscle, as mentioned in the notes of the cases; but at the same time does not necessarily become dissolved in the blood plasma, at all events entirely, some of it remaining in amorphous masses. This appearance, which was seen in two of the cases, has not, I believe, been observed before. It is also worthy of note that the corpuscles do not form rouleaux, but appear to cohere by their edges, sometimes even appearing to become partially fused with one another. The *colour* of the corpuscles is much less intense than in health, if those of the small globular variety be excluded; the colourific intensity of the blood, as determined by the hæmoglobinometer, being often found to be much less than can be accounted for merely by the diminution in number of the corpuscles. Eichorst describes the liquor sanguinis as being of a serous amber colour, and states that it coagulates with difficulty, but this has not been borne out in these cases; neither can I agree with him that the colourless protoplasmic granules found in normal blood are completely absent, as in each case they were noted as being, if anything, more numerous than usual.

In three of these cases it was found that on rapidly drying a specimen of blood taken from the finger, the red corpuscles readily broke down, sometimes disappearing entirely, while sometimes a coarsely granular appearance was left. These specimens showed after a time, in place of the corpuscles, an aggregation of rhombic crystals of hæmoglobin, the spontaneous appearance of which in anæmic blood has not apparently been previously noticed. The fact of their appearance in this manner without special preparation is the more curious when it is remembered that under ordinary circumstances it is practically impossible to obtain hæmoglobin crystals from normal human blood. From the blood of some of the lower animals crystals may be obtained with the greatest ease, notably from the guinea

pig and rat or mouse; but human hæmoglobin, being soluble in a much greater degree, is consequently much more difficult to obtain in the crystalline form, the order of solubility, and so of facility of crystallisation, being given by Gautier in the following order for various animals—(1) rat, guinea-pig, squirrel, and then, with a great interval, (2) cat, dog, horse, and man. In two of the cases described above, in which the corpuscles persisted, no crystals were developed, but amorphous masses of brown pigment were seen scattered among the corpuscles, the difference possibly being that in the one case hæmoglobin and in the other hæmatin only was extruded, the globulin then being retained in the stroma. That hæmatin, which is non-crystallisable, and globulin should be capable of dissociation thus is borne out by the presence in old blood clots of pigmented crystals of hæmatoidin, which is apparently identical with iron-free hæmatin. In two

Showing crystals starting from red corpuscles. (Case 3.)

instances the specimens of which were taken from Case 3, the crystals were seen to be directly derived from the red corpuscles (Figs. 2 and 3), and their formation was watched from time to time. An exactly similar appearance is described by Dr. Lionel Beale as having been witnessed by him in the case of hæmoglobin crystals obtained from guinea-pig's blood, the crystals being comparatively large when springing from an entire corpuscle—smaller when arising from the portions of one which has partially broken down.

Considerable difficulty is experienced in preserving specimens of hæmoglobin crystals as permanent objects. The beautiful crystals from guinea-pig's blood are readily obtained, but, in whatever way they may be mounted, generally lose brilliancy and the sharpness of their angles after a time. Consequently, it was to be expected that human hæmoglobin, being so exceedingly soluble, would not be very permanent, and this unfortunately appears to be the case, as many of my specimens have deteriorated considerably since they were first prepared. The only description of crystals occurring in the blood in disease is apparently that of Charcot, who speaks of small lenticular crystals, named after him, as having been noticed in the blood in leucocythæmia. Gowers states that they are a post-mortem phenomenon, and also adds that they are not peculiar to this disease. These crystals, which Charcot considers to be of a proteid nature, differ in every respect from those just described, one important point of difference being that in these cases of pernicious anæmia the destruction of the red corpuscles was a necessary antecedent to the appearance of the crystals, while in Charcot's cases it was not so.

It is necessary to add a word or two on the treatment of this disease, since the appearances described seem to have a bearing, if only a negative one, on this point. In all the

cases arsenic was prescribed in the form of liquor arsenicalis, and with the best results. To Dr. Byrom Bramwell we owe not only some of the earliest descriptions and the first real investigation of this disease, but also the use of this drug in treatment, in support of which may be mentioned the not uninteresting fact that in the cases in which crystals of hæmoglobin were at first obtained none could be found after the patient had been for a few days under the influence of arsenic, even though the blood did not at the same time show any very considerable change in the number of corpuscles or in the amount of hæmoglobin present, while in two or three subsequent cases in which the drug had been administered before the patient was examined, but in which the hæmocytometer showed a percentage of corpuscles as small as that in the cases in which crystals were obtained, none were ever found. These facts appear to show pretty distinctly that arsenic has a very immediate action for good on the blood in this disease, especially as all the patients, notes of whose cases have been given, left the hospital greatly relieved, if not absolutely cured. One of these, it must be

Digitized by Google

stated, has lately been readmitted, and it is possible that the disease may reassert itself in all of them after a time, as, it seems, is not unfrequently the case; still, the effect of this drug, at any rate for the time, appears to be little short of marvellous.

In conclusion, my best thanks are due to Dr. Bristowe, to whose kindness I am indebted for permission to make use of the notes of the cases that have been quoted.

York-road, S.E.

CASE OF MYELOID SARCOMA, INVOLVING BOTH SUPERIOR MAXILLARY BONES, TOGETHER WITH THE HARD AND SOFT PALATE;

REMOVAL OF GROWTH WITH THE GREATER PART OF BOTH BONES; RECOVERY.[1]

BY F. BOWREMAN JESSETT, F.R.C.S. ENG.,
SURGEON TO THE CANCER HOSPITAL.

S. G. B——, a married woman, aged thirty-five years, was admitted into the Brompton Cancer Hospital on Oct. 31st, 1886, with a large growth involving the whole of the hard palate, and projecting into the mouth to the line of the teeth on both sides. The patient's grandfather died of epithelioma of the lip; no further history of cancer in the family; father and mother both living and healthy; no history of phthisis or syphilis. She first noticed a lump in the hard palate twenty-one months ago, which grew rapidly until it attained the size of a bantam's egg and projected considerably into the mouth, interfering with mastication and speech. Six months after first noticing the growth she went to Guy's Hospital, where she was operated upon by Mr. Clement Lucas, through whose courtesy I have obtained from Mr. Targett, the surgical registrar of Guy's Hospital, the following particulars:—"She was admitted into the hospital on June 11th, 1885, under the care of Mr. Clement Lucas for a myeloid sarcoma of the hard palate which had existed about six months. On June 16th, 1885, Mr. Lucas excised the tumour with scissors, and then scraped the base, applying tannic acid to stop hæmorrhage; no portion of the hard palate was removed, and on June 28th she was discharged, the wound having granulated nicely." In June, 1886, she was admitted into St. Thomas's Hospital, under Sir W. Mac Cormac, with extensive recurrence of the disease. On examination it proved to be a very vascular sarcoma, with definite myeloid cells and spicula of bone. She noticed the edges of the opening in her palate, the result of the removal of the tumour, swollen and tender about three months after she left Guy's Hospital, and from that time the growth extended rapidly.

State on admission.—There is an irregular mass implicating the whole of the hard palate and the inner aspect of the gums on both sides, as far forward as the first molar tooth; the soft palate is also infiltrated with the disease to within a quarter of an inch of its posterior edge; the growth extends upwards into both nostrils, but more so on the left, where it is seen protruding for some considerable distance, presenting much the appearance of a large polypoid growth. The patient cannot breathe through either nostril. By digital examination of the pharynx, the tumour is felt pressing back upon its posterior wall, and it is impossible to ascertain how high it extends posteriorly. The patient suffers comparatively little pain from the growth, but complains chiefly of the difficulty in eating, the movement of the tongue and capacity of the mouth being limited by the growth (which is the size of a large lemon) projecting into it. There has never been any hæmorrhage. The tumour feels hard but elastic to the touch, is firmly fixed, and appears to extend deeply into the antrum on either side. There is a slight fulness over the left antrum, but the teeth on both sides are very good, and in no degree loosened.

At the urgent request of the patient, I consented to endeavour to remove the growth, although at the time I feared I should not be able to do so without removing the whole of both the superior maxillary bones; but I determined in the first place to endeavour at any rate to leave the infra-orbital plates intact if possible, and I hoped to be able to accomplish this, as from the history of the case it appeared clear that the growth commenced solely from the hard palate or from the alveolar process. On Nov. 9th the patient being placed fully under the influence of an anæsthetic I made a most careful examination of the tumour, but could find little more than I had done previously. The growth, however, extended so far back and appeared so firmly fixed that I had some misgivings as to the result of the operation.

Operation.—I made two incisions, extending from either angle of the mouth, upwards and outwards towards the inner angle of the orbit; I then reflected the flap thus formed, which included the nose, upwards over the forehead, and in this manner thoroughly exposed the whole of the front of the growth and superior maxillary bones. I next, with a fine incision saw, divided both bones about half to three-quarters of an inch above and parallel to the alveolar processes through their whole extent, and, with a raspatory used as a lever, separated this portion of the bones from the upper and remaining halves. Having thus loosened this portion of the bones with the tumour attached, I seized it with the lion forceps, and at the same time introduced the index finger of my left hand into the pharynx behind the growth, and in this manner was enabled gradually to remove the whole of the disease, with the exception of that portion which had grown into the antrum on the left side. This, however, was quite detached, and was subsequently easily removed by means of Volkmann's spoon. There was scarcely any hæmorrhage, and the disease appeared to have been entirely limited to the portion of bone removed, having grown from thence upwards and insinuated itself into the antrum and between the ethmoidal spongy bones. The skin flaps were next brought together with harelip pins and one or two horsehair sutures, and the whole surface dusted over with iodoform. The patient, who stood the operation remarkably well, was returned to bed. She was fed for the first twenty-four hours with nutrient enemata, after which time she took food by the mouth from a feeding-cup with a piece of indiarubber tubing attached, sufficiently long to pass over the root of the tongue.

Nov. 10th.—Patient has passed a good night. Temperature normal.—12th: Patient still doing well. The mouth is kept washed out with a solution of boro-glyceride; there is very little discharge; takes nourishment well.—15th: Two of the harelip pins removed. Wound healthy; no pus.—16th: The remaining harelip pin removed. Wound quite united. The patient from this point made an uninterrupted recovery, and is now (February 24th, more than three months after the operation) quite well. Her speech is peculiarly good; in fact, with the exception of a few letters, she speaks well. There is little or no deformity. She is now being fitted with a plate, by which means it is hoped to enable her to masticate fairly well.

Remarks.—This case represents well one of those rare cases in which the practice of removal of the greater part of both the superior maxillary bones may be practised with advantage. In performing the operation I preferred adopting the primary incision as suggested by Heyfelder, as, from the size of the growth and the uncertainty of its deep attachments, I thought these incisions would afford the greatest possible amount of room for the removal of the tumour, and also in case of deeply seated hæmorrhage occurring during or after its removal these incisions would enable me to obtain the best view of the deep parts. After having fully exposed the tumour by reflecting the flaps upwards, instead of attempting to pass a chain saw through the spheno-maxillary fissure, which in this case would have been impossible to accomplish, I preferred to saw through the maxillary bones from the front, and then by inserting a chisel into the divided bone to separate the alveolar processes and lower part of the bones from the upper. By this means I avoided wounding the growth, which was very vascular, and I was enabled to remove it with its attachment entire. Had I persevered and thrust the chain saw through the spheno-maxillary tissue and sawn through the bone from behind forwards, it is evident that I must have divided the growth as well, and in all probability met with very considerable hæmorrhage. By adopting the method of dividing the bones, I was enabled to preserve the pterygoid processes of the sphenoid bone intact, which is of very great importance. Had the disease extended deeper than it did, by removing the lower portions of the bone by this method it would have been easy by means of

[1] Read before the Medical Society of London.

Digitized by Google

the gouge or gouge forceps to remove as much more as might have been necessary. Doubtless, this method of proceeding has been adopted by other surgeons, but I have been unable to find any case so operated on recorded. A point of interest about the growth is its character. The original growth when removed at Guy's Hospital is reported to be myeloid sarcoma. Again, when the patient presented herself at St. Thomas's Hospital the growth was described as a myeloid sarcoma. The appearance of the tumour now, however, has appeared to have undergone a change, for there are only a few myeloid cells to be seen, while the bulk of the tumour seems to be made up of a firm fibrous stroma interspersed with a large number of small round cells. Another interesting point is that when Mr. Lucas removed the growth in June, 1885, he did not remove any of the hard palate. Now, however, the whole of the hard palate is absorbed, having been destroyed by the tumour. There is no doubt the growth commenced in the periosteum of the hard palate, for Mr. Lucas is reported to have scraped the base, after removal of the growth with scissors, and from its point of origin the tumour grew upwards and right and left, absorbing the bony structures as it extended, at the same time pushing its way outwards into the cavities of the antra, and upwards between the ethmoidal spongy bone.

Upper Wimpole-street, W.

A FEW FACTS CONCERNING THE RECENT PREVALENCE OF WINTER DIARRHŒA.[1]

By SHIRLEY F. MURPHY,

LECTURER ON HYGIENE AND PUBLIC HEALTH, ST. MARY'S HOSPITAL.

I HAVE thought that our Society might well have before it a few facts which I have been able to glean concerning the recent prevalence of diarrhœa during the winter months. The subject was first referred to in a paragraph in THE LANCET of Feb. 5th, which also contained the following week a letter from Mr. C. H. Taylor of the West London Hospital, stating that diarrhœa was prevalent in Fulham, Chiswick, and Hammersmith; and the *British Medical Journal* of the same date published a communication from Dr. Norman Kerr telling the same story for the neighbourhood of Regent's-park. Later, other correspondents bore witness to the existence of epidemic diarrhœa in St. James's, Bayswater, Marylebone, Clapham, Lewisham, Penge, Kingston-on-Thames, Kent, and even as far from London as Lancashire and Aberdeenshire. The reports of the symptoms from which the patients suffered fairly well agreed. In all cases there was diarrhœa, in the majority abdominal pain, vomiting, cramps in the limbs, great depression, and a symptom of particular interest -- high temperature. In a few the fact was noted that the patients also suffered from hæmorrhage from the bowels. In many instances the sufferers were attacked in the night, and often in groups, suggesting community of cause. We may assume therefore, in the first instance, that the epidemic, wherever it manifested itself, was of the same nature, and that some of the symptoms to which it gave rise were those not usually met with in ordinary diarrhœa, and that, regarding it as diarrhœa, the disease occurred at an unusual period of the year. We are led, moreover, to conclude that, notwithstanding the area which its operations covered, it is in the highest degree probable that the cause in each locality was the same. And I may go further, and say that this cause was not related to any climatic condition; for, if we examine the dates of outbreaks in public institutions situated near to each other, and therefore subject to the same climatic conditions, we do not find that these dates exactly correspond; and, further, some institutions also in the neighbourhood of those which were invaded escaped altogether. The cause must, nevertheless, be one capable of operating over large extents of country.

My own opportunities for learning some particulars of this illness were practically limited to its behaviour in a special hospital in Central London, which I first visited for that purpose on Jan. 27th. I was informed by the senior house-surgeon, who had taken great interest in the matter, that half the inmates of the institution about two months before had been attacked suddenly with diarrhœa, the patients alone suffering and the staff altogether escaping. On Jan. 25th the incident repeated itself, nearly fifty persons on this occasion being attacked. The distribution of the disease in the hospital is of importance; for again, on the second occasion, the patients were, with trifling exceptions, the only sufferers. The patients are resident in wards situated on three floors; those on each floor taking their meals mostly together. On the first floor are beds for thirty women, on the second floor beds for forty men, and on the third floor twenty-six beds, twenty-one of which are occupied by men and the rest by children. Of the patients resident in the hospital at the time of my visit, I found that on the first floor there were attacked on Jan. 24th (Monday), in the morning one, in the evening three; on the 25th (Tuesday), in the morning two, in the evening six; on the 26th (Wednesday), in the morning one. On the second floor there were attacked on Jan. 24th (Monday), in the evening one; on the 25th (Tuesday), in the morning eighteen. On the third floor there were attacked, on Jan. 24th (Monday), in the evening five; on the 25th (Tuesday), in the morning six. Or, considering those on the different floors together—on Monday, Jan. 24th, ten were attacked; on Tuesday the 25th, thirty-two; and on Wednesday the 26th, one; the majority of the attacks occurring while the patients were in bed at some period of the night.

The most striking circumstance in the outbreak is the almost complete immunity enjoyed by the staff. Of twenty-two persons engaged either in attendance upon the sick or in domestic duties, but two suffered from diarrhœa, and these were nurses, both of whom were attacked in the early morning of Tuesday, Jan. 25th.

To enable the exact incidence of the disease upon the patients to be determined, and for the purposes of further inquiry, I ascertained the condition of health of those who had been discharged from the hospital for some time previously, and in this manner elicited information that no patient who left the hospital before Jan. 24th was attacked. On Thursday, Jan. 20th, three patients were discharged, and on Friday, the 21st, three; on Saturday, the 22nd, six: none of whom suffered. On Sunday, the 23rd, no patients were discharged; on Monday, the 24th, six patients were discharged, three of whom were attacked early the following morning at their own homes. Whatever cause, therefore, gave rise to diarrhœa probably came into operation after the patients left on Jan. 22nd—i.e., after midday dinner on that day. Of patients newly admitted into the hospital, three admitted on Jan. 20th were each attacked; of two admitted on the 21st, one was attacked; and of three admitted on the 22nd, two were attacked. None were admitted on Sunday, Jan. 23rd. Five were admitted on Jan. 24th, all of whom escaped. Two were admitted on Jan. 25th, both of whom escaped. The cause of the outbreak therefore probably ceased to be operative before the patients were admitted on Monday, Jan. 24th—i.e., the cause was operative only some time between midday on Saturday, Jan. 22nd, and midday on Monday, Jan. 24th.

It becomes important, therefore, to ascertain the effect of this cause upon the patients *who were in the hospital at this particular time*, changes by admissions and discharges having taken place before my visit. There were sixty patients in the hospital between Jan. 22nd (Saturday), midday, and Jan. 24th (Monday), midday, of whom forty-three were attacked with diarrhœa, either within the hospital or immediately after their return home, giving a percentage of 76·6. Of the staff I have already said there were twenty-two, of whom two were attacked, or 9 per cent. This difference is so great that I was compelled to regard the condition causing the diarrhœa as one with which the patients must be specially related, and this view was strengthened by the fact that the two affected members of the staff were nurses who may likely enough have come into accidental relation with this condition.

At this period I was not aware that the disease was prevalent in other parts of England, and I was led to examine the incidence of attack upon patients taking milk, water, and other articles of food. Of those who drank unboiled water at their meals there were thirty-three, of whom twenty-five were attacked, or 75·7 per cent., being practically identical with the general average. Of those who drank no water except that which they had in their tea, and which had therefore been boiled, there were twenty-six, of whom twenty-one were attacked, or 80·7 per cent. Drinking water

[1] Read at a meeting of the Society of Medical Officers of Health, May 20th, 1887.

Digitized by Google

or abstaining from water did not therefore affect the probabilities of attack. Again, forty-four patients drank uncooked milk instead of beer, and of these thirty-four were attacked, or 77·2 per cent., a proportion equal to the general average. Of fifteen patients who took no milk except in tea, thirteen were attacked, or 86·6 per cent. Drinking or abstaining from milk cannot therefore be said to have affected the probabilities of attack. Nevertheless, the large proportion of attacks among patients, and the immunity enjoyed by the staff, strongly indicated some article of food as responsible for the occurrence. The senior house-surgeon was good enough to prepare for me a complete list of all the articles of food consumed in the hospital. I may at once eliminate from further suspicion the following:—Milk, because the supply was common to staff and patients, because of the evidence already adduced, and also because the same farms supplied milk to another large hospital, which remained free from disease. Water, because it was consumed by staff and patients, and because of the evidence already adduced. The possibility that the local contamination of a cistern was responsible for the outbreak may be set aside by consideration of the fact that separate cisterns supplied the different floors. Tea and salt may be eliminated, because the supply was common to staff and patients. Meat and potatoes, because the supply was common to staff and patients. Beef-tea, because it was only consumed by a few patients. Beer, because those who did not drink beer were also attacked. Bread and sugar, because the same articles consumed by the patients were also supplied to the servants, none of whom were attacked. Rice, because no fresh supply had been received for a long time previously, and the children had been eating rice daily without injury. I may also refer to the fact that other institutions and other parts of the country were invaded, having different milk, water, and meat supplies.

There is but one article of food I am unable to exculpate, and to the possibility of this being the cause of a widespread outbreak I would desire to direct the attention of the Society. I refer to butter, which in the method of its distribution in the hospital in the first instance raises a presumption that it may have been concerned in producing this curious disease. Three qualities of butter were supplied to the institution—(*a*) that provided for the medical officers and matron, (*b*) that provided for the nurses and servants, and (*c*) that provided for the patients. The patients' butter is received on every weekday at 10 A.M., and is used for tea and supper the same day and for breakfast the following day, on Saturdays the supply being increased to last until breakfast on the following Monday morning. If we assume that the butter received for the patients on Saturday, Jan. 22nd, possessed purgative properties, there is ample explanation of the illness of all the patients who suffered from diarrhœa. That all were not attacked at the same time, and that some escaped, may be due to some unequal distribution of the active principle throughout the butter, or perhaps to some difference in the quantity consumed. There remain the attacks of two nurses, who, it may be mentioned, suffered less severely than the patients from this malady. I have no other explanation to offer on this point than that they must have eaten some portion of the bread-and-butter not required for the patients. Those who are intimate with hospital life will know that this is no unusual event. Thus far as to this particular hospital. The difficulty which stands in the way of the acceptance of this theory is the fact that other institutions—many persons not living in institutions, and other parts of the country have also shared in the prevalence of diarrhœa.

English butter is made upon the farm on which the milk is produced, and the few pounds which each farm is able to contribute could not be sufficiently widely distributed to give rise to an occurrence such as that we have under consideration. But the butter which I have been led to suspect was that provided for the patients, and low-priced butters come largely from abroad. In other countries butter is not always manufactured on the farms on which the milk is produced, but large numbers of farms send their milk to central depôts, where, I am told, the milk of hundreds of farms is mixed together, made into butter, and colouring matter added, which always gives to it a uniform colour and flavour. This is sent over in enormous quantities to the English middle-man, who distributes it to local vendors, from whom it reaches the consumers. In this manner any capacity which the milk from any farm might possess to cause diarrhœa would, if due to an organism, have the possibility of being multiplied by admixture of this milk with other milk, and thus its effects might be felt in many places. Or perhaps the method of treatment of the butter in some central depôt might be concerned in conferring upon it this power, or possibly by the development of some chemical poison it might have acquired this special property. The symptoms of the sufferers, indeed, remind us of the observations of Dr. Victor C. Vaughan of Michigan concerning the effects of a ptomaine he found in cream. It is, under any circumstance, conceivable that butter which possesses this property might be distributed through different channels over a large area of country, and thus induce diarrhœa in one district or institution at one time and in another at the same or at a different time.

I have not had the opportunity of extending my inquiries sufficiently to enable me to thoroughly sift the evidence that could be obtained outside the institution with which I was concerned. I therefore prefer to leave the subject where it is, but I may mention incidentally that one large hospital which also suffered heavily received its butter from the same source as that which came under my own observation, and that another suffering very partially required the patients to supply their own butter, thus giving opportunity for it to be procured from many sources, of which perhaps one only was identical with that under suspicion. This difference in the method of supply may perhaps account for the smallness of the number of persons affected in some institutions. I do not wish now to do more than urge—1st, that the nature of the epidemic of which we have recently had experience points to an article of food as the cause; 2nd, that the facts learnt at one institution, where they were carefully observed, point especially to butter; and, 3rd, that any objection to this theory, which is based on the method of distribution of butter made on English farms, falls to the ground when the distribution of foreign and of artificial butters is considered. In conclusion, I would desire very cordially to thank Mr. E. Treacher Collins, whose active assistance has enabled me to ascertain the facts upon which this story is based, and to whose accurate observation I am very greatly indebted.

DEATH FROM IMPACTION OF GALL-STONES.

BY A. GLOVER WILLIAMS, M.D., M.R.C.S.,
SURGEON TO THE BRIXTON DISPENSARY.

ON October 13th, 1886, I was called to see Mrs. B——. She was a woman of dark complexion, with rather an anxious expression, and was markedly jaundiced, the conjunctivæ being of a deep yellow. She was fairly well nourished. I was told that three months ago she was seized with pain below the right ribs, which gradually became intense; it was more or less paroxysmal in character, accompanied by violent sickness, and followed in a day or two by yellowness of the skin. A medical man was called in, who said she was suffering from the passage of gall-stones. She suffered from the pain and sickness at short intervals until three weeks or a month ago, when the pain left her; but the sickness increased, notwithstanding, until she could keep nothing down; the jaundice also deepened. Her friends told me that she had been somewhat addicted to drink. She was under my care from October 26th to November 12th, 1884, and was then suffering from symptoms of gall-stone colic—viz., acute pain in the right hypochondriac region, with sallowness of the conjunctivæ, which did not amount to jaundice; the urine contained some bile, and the fæces were pale—i.e., clay-coloured; the motions were searched for gall-stones, but none were found. In July, 1885, she again came under my notice with the same symptoms. There was no actual jaundice on this occasion, and no gall-stones were found in the fæces. In March, 1886, she had a similar attack, but on this occasion she was jaundiced; the pain then left her suddenly, but her recovery was gradual. She says that her father had some operation performed on his lip, but she does not know what for.

The patient's present condition (Oct. 13th, 1886) is as follows: She has lost all pain, but suffers from constant sickness. She retains nothing; even the medicine is returned. The vomit is of a dark-greenish colour, almost wholly fluid, and about the consistence of thin gruel. The bowels are

Digitized by Google

open, somewhat relaxed; motions greyish-white in colour. She is very restless, and gets but little sleep. The urine is very dark, and contains bile. The liver is felt below the ribs; the upper line of dulness is lower than natural (at seventh rib) owing to increased lung resonance, so that the liver dulness only measures vertically three inches in the nipple line. At the junction of the umbilical and right lumbar regions, and about three inches from the edge of the right ribs, a hard mass about the size of a large walnut is felt on deep pressure; it is somewhat tender and quite immovable. Ordered iced milk, milk and soda-water in small quantities with brandy, and a mixture containing bismuth, hydrocyanic acid, and opium.

Oct. 15th: Sickness somewhat less. Has kept a little down. Medicine has not been returned.—17th: Not so well; sickness is worse; has not been able to keep anything down. Ordered nutrient enemata of beef-tea, egg and brandy, three times a day.—19th: Sickness still continues; is very restless; cannot sleep at night. Ordered white of egg by mouth, as well as the enemata, also a pill containing half a grain of opium every four hours.—20th: No diminution in sickness. Ordered an effervescing draught, with hydrocyanic acid and opium.—21st: She is much worse, and in a semi-unconscious condition, from which she can be roused to a certain extent. No sickness since 3 A.M.; pulse frequent and very feeble. Ordered two drachms of brandy every hour. From this condition she never rallied, but, becoming more unconscious, died at 5 P.M.

Necropsy.—Body fairly well nourished; skin and conjunctivæ intensely jaundiced. On opening the abdomen, a good layer of fat was noticed in the abdominal wall. The liver was seen to project about an inch below the edge of the right ribs; it was somewhat larger than natural, and the increase was most marked in the left lobe. On section, the central zone was well marked, the outer being pale. The gall-bladder was small, and adherent to the under surface of the liver; its walls were much thickened. On opening it, it was found to contain about a tablespoonful of thick greenish fluid, and thirteen or fourteen gall-stones, varying in size from a small pea to that of a hazel-nut; most of the stones were marked by facets. The cystic duct was much dilated, and contained two gall-stones about the size of small hazel-nuts. The common bile-duct was much dilated, and was at least as large as a man's thumb. At the point of entrance into the duodenum three large gall-stones were impacted in a triangular fashion, two being in front and one behind; they completely blocked the opening into the duodenum, were of the size of large hazel-nuts, angular, and marked by facets; the remainder of the common duct contained three stones, rather smaller than these. The hepatic duct was dilated, and contained two stones, which were angular and marked by facets. The duct from the left lobe was much dilated, and contained one stone about the size of a large pea; the duct from the right lobe was not much larger than natural, and contained no stone. The spleen was congested and very friable. The kidneys were slightly puckered, and the capsules somewhat adherent. The glands in the lumbar region lying to the right of the bodies of the vertebræ, and behind the duodenum and head of the pancreas, were converted into a hard calcareous mass about the size of a walnut. There was no bile stain on the mucous membrane of the duodenum.

Remarks.—The rarity of death from impaction of gall-stones uncomplicated by other disease alone makes this case interesting, only two cases being quoted in Murchison's "Diseases of the Liver," and these do not occur in his own experience. The diagnosis was in some degree complicated, owing to the small tumour felt at the junction of the umbilical and right lumbar regions. This, which proved to be a calcareous mass of glands, suggested some malignant disease of the pylorus, duodenum, or head of pancreas; but the character of the pain, the interval between the patient's illnesses, and the freedom from symptoms, together with the fact that there was comparatively very little loss of flesh, pointed to gall-stones as the chief element in the case. Another point of interest was the cessation of pain for so long a period before death, without any improvement in her other symptoms. Then there was no enlargement of the gall-bladder, owing to the obstruction of the cystic duct—a point which usually helps the diagnosis. As to the immediate cause of death, it was no doubt due to cholæmia and the exhaustion consequent upon the continued sickness. Bile had evidently not entered the intestines for some time. In conclusion, could anything have been done in the way of an operation (cholecystotomy) in this case? In my opinion decidedly not, as the gall-bladder was small and firmly adherent to the under surface of the liver.

Brixton-hill, S.W.

GOITRE IN ANIMALS.

BY ALLEN THOMSON SLOAN, M.D. EDIN.

THE question of goitre among animals appears to have been little studied, and it is difficult to get any literature on the subject. For my present information I am indebted to the works of St. Lager and Baillarger, and also to the kindness of Principals Williams and Walley of the Veterinary Colleges, Edinburgh, whose opinions, however, are rather opposed to each other. According to St. Lager, the thyroid gland exists in all mammiferous animals, birds, and reptiles. It is wanting among many fish—such as the perch, mackerel, salmon, herring, turbot, and sole; but it exists in the carp, sturgeon, eel, and shark. In many mammals—as the camel, alpaca, nylghau, hartebeest, dog, warthog, porcupine, and kangaroo—the isthmus is wanting, and the two lateral lobes are quite disconnected; whilst in the female carnivora the isthmus is very small in relation to the size of the lateral lobes (Turner).

Naturalists have wrongly applied the term "goitre" to the enlargement of the throat seen in certain reptiles—such as the chameleon, iguanas, lizards, and some species of toads. Among these the skin of the neck hangs down in projecting folds. The term "goitre" has also been applied to the swollen necks found in certain birds—such as the pouter pigeon, the cormorant, the pelican, and some vultures, all of which have enlargement of the throat quite distinct from the thyroid gland. Aristotle, Pliny, Galens, and Ætius have remarked that pigs are subject to swellings of the glands of the neck. Galen expresses himself thus: "Graeci strumas appellant χοιράδες a porcis in quoram gutture adenosi quidam tumores reperiuntur." Paul D'Egine said that these referred to scrofulous tumours, but Pliny, in his Natural History, says positively that pigs are subject to goitre owing to the bad water they drink. Vegèce, in his "Treatise on the Veterinary Art," speaks of scrofulous tumours of the parotid, and goitres which are seen sometimes in mares. Goitre has been seen in dogs and pigs in many parts of Switzerland by various observers. It has been noticed in sheep and cattle in Switzerland, Wurtemburg, the valley of the Danube, in the Himalayas, in Siberia, in Brazil, and the United States. Rudolp and Rupp have seen hyænas goitrous. Gustave Ruddé has seen in Siberia, near the Chinese frontiers, antelopes with goitre. He thought at first they formed a new species, and called it "antelope gutturiosa"; but as he only saw them in districts where goitre also affected man, and not in those where it was absent, he came to the conclusion that it was pathological.

In Russia, Central America, the United States, and in the Canton of Geneva horses have been seen goitrous. M. Baillarger, in a paper read before the French Academy of Sciences,[1] gives the result of his researches undertaken in the departments of the Savoy and of the Isère. In many localities in Maurienne, St. Jean, and St. Michael, he found among mules hypertrophy of the thyroid gland in much greater proportion than among man. In a stable of Modane, out of twenty mules nineteen had goitre. In the department of Isère, out of thirty mules employed in the mining works no less than twenty-three had goitre. In the normal state the thyroid gland of mules is about the size of a chestnut, but in these cases it had attained the size of a hen's or turkey's egg. As a rule, the goitres were very movable and caused no pain; but in three cases they compressed the trachea, and produced breathlessness during strong muscular effort, causing the animals to kick. The hypertrophy affected both lobes of the gland, or one only, and in the latter case more often the left. At Allevard, Dr. Niepce confirmed these observations. The existence among mules of a special tendency to hypertrophy of the thyroid seems to be placed beyond doubt, and does not exist to the same degree among other domestic animals. Horses are often attacked with goitre, but the proportion is much less. In certain conditions, however,

[1] Sur le Goitre des Animaux. Compte Rendu, Académie des Sciences, 1862.

Digitized by Google

the frequency is very great. At St. Jean de Maurienne four out of seven horses of the gendarmes were affected with goitre after a residence of less than two years in the place. This case was all the more remarkable because these horses were well fed, carefully groomed, and kept in a well-lighted and well-ventilated stable. After horses, dogs are most liable to hypertrophy of the thyroid. Finally, one finds it in cats, cows, sheep, goats, and pigs. It is impossible not to attach goitre in animals to the same endemic causes which produce it in man. Among a great number of these animals in Swiss localities, it was rare to find a thyroid of normal size. Professors of veterinary medicine have considered goitre excessively rare among animals. I believe this rarity only exists in healthy localities, but it is otherwise where goitre and cretinism are endemic. It is difficult to account for its special prevalence among mules, but it is interesting to note its occurrence among sterile animals, when sterility is one of the characters of cretinism. In regard to cretinism few observations have been made. Raynard has seen in goitrous dogs a stupidity comparable to idiocy, and Rougieux has observed the same degradation in dogs and horses. St. Lager asked several persons who possessed goitrous animals in Savoy, Switzerland, and Piedmont, and all have assured him that the hair becomes rough and coarse, the voice hoarse, and the memory obliterated. They become lazy, and finally reach a state of torpor which it is quite justifiable to compare to cretinism. Most interesting are the above observations when viewed in the light of the recent experiments of Mr. Victor Horsley, who, in showing the relative value of the thyroid gland in different animals, demonstrated how its removal produced sooner or later grave nervous effects in the donkey, pig, cat, and dog, according to the functional importance of the gland in each.[2] Alibert says that sheep and calves not unfrequently die from the effects of goitre.

Observers in India confirm the fact that goitre affects animals in those countries where it is endemic. Thus Mr. Greenhow[3] says: "At Hissaurpore, a village on the Surjoo, about twelve miles distant from Seerora, dogs and other animals are affected with goitre. Mr. Bramley[4] noticed the same curious circumstance in Nepaul, for he mentions, "on one occasion a goat brought forth a kid with a goitre as large as its head." Puppies of a month old, bred from English dogs, are very frequently affected by it, as are also lambs." in 1824 he observed this tumour in camels at Purneah, and crows are likewise said to be affected with it at the same place. Dr. Campbell[5] has seen horses and lambs goitrous on the borders of Gunduk, and also many animals in Nepaul, among others buffaloes. Dr. MacClelland reports its occurrence among dogs and cats in the Himalayas. While Mr. Brett, in his "Surgery of India," says: "Bronchocele is congenital in animals in Nepaul; almost the moment the animal is born it expires"—a fact noted also by Dr. Campbell.

Principal Walley of the Dick Veterinary College, Edinburgh, is of opinion that goitre in animals is an extremely rare disease, and that the cases reported have been generally mistaken for struma. In horses especially it seldom occurs, and these also are very free from struma. The only typical case of goitre he has seen was in a horse belonging to the late Emperor Napoleon, which was bought by Mr. Pender, M.P. for Wick. Owing to the enlarged thyroid the animal was afflicted with "roaring," so its removal was attempted. During the operation, however, the horse in its struggles broke its back, and had to be killed. Mr. Walley thinks that true cases of goitre do occur among pigs, and these of all domestic animals are most commonly affected with scrofula. He considers it rare in dogs and cattle. I have never seen a case of goitre in an animal, but it is interesting to note that in Cumberland, where it exists as endemic disease among man, that cattle are notoriously subject to scrofulous enlargements of the glands of the worst type.

Principal Williams, of the New Veterinary College, Edinburgh, informs me that goitre is prevalent in horses, sheep, and cattle in Derbyshire and some parts of Wales, where magnesian limestone prevails, but that he has seen it pretty common in places quite independent of this. In his practice round about Edinburgh he finds it occasionally occurring in young foals, which fact he associates with bad ventilation. It is sometimes congenital; in one case a mare of his own gave birth to a foal that was goitrous. It is more rare among dogs, though it sometimes affects young ones, disappearing as they grow older and under treatment. About twelve years ago an epidemic of it affected Lord Polwarth's lambs at Mertoun, Berkshire. In his "Principles and Practice of Veterinary Surgery," he writes thus: "Cysts in the thyroid body constitute bronchocele; they are said to be caused by the water which the animals drink, and that if the water be changed they will disappear. But I have some doubt as to the truth of the statement that bronchocele is solely caused by the presence of magnesian lime in the water, as I have seen well-marked cases in young foals and in large flocks of lambs where this could not possibly be the cause. Doubtless, it is found most abundantly on the magnesian limestone formations; but it cannot be denied that low situations, or a damp atmosphere upon elevated situations, will act as causes of bronchocele."

Both these professors have several times seen the thyroid completely destroyed by inflammation and suppuration, and the animal remain afterwards perfectly well. Neither of them have had any experience in regard to removal of the gland, as cases necessitating this operation are hardly ever met with.

Artificial production of goitre in animals.—Various experiments have been made upon animals with the view of artificially producing goitre, but without any trustworthy results. According to St. Lager, both he and Baillarger administered preparations containing carbonate of lime and magnesia to dogs for a period of six months, without any enlargement of the thyroid gland ensuing. The same writer gave dogs and guinea-pigs sulphuret and sulphate of iron and other metallic salts for some months, but with negative results. One day, however, in his own house, he caught a mouse, and to his astonishment it had a goitre, which he thought might have been caused by its eating cinders of a certain coal which contained sulphuret of iron. Accordingly he experimented on a dozen mice, giving them sulphuret and sulphate of iron, baryta, fluorine, and natural bitumen. At the end of three months three only had enlargement of the thyroid perceptible both to sight and touch. These three had added to their food sulphuret and sulphate of iron. Many doctors of Lyons are reported to have seen these animals, but the experiments can hardly be said to be trustworthy or at all convincing. The salts of iron have been long administered in medicine, and for the last few years not only the sulphate but the sulphide of iron have frequently, and for lengthened periods, been given in the treatment of anæmia, with none other than a beneficial effect.

GENERALISATIONS REGARDING THE

PATHOLOGY OF ABNORMAL GROWTHS IN MAN AND ANIMALS, AND THEIR EXPLANATION ON THE EVOLUTION THEORY.

By ALBERT GRESSWELL, B.M., B.A. OXON., M.R.C.S.

No branch of comparative pathology has received more careful study than that which deals with the mode of growth and variations in the histological structure of the various tumours, malignant and benign. In these short notes I propose to restrict myself to a cursory survey of the etiology of abnormal growths, not criticising views which are generally held, and not dealing with the actual or immediate cause, but suggesting a general basis which may be regarded as the ultimate cause to which such abnormal manifestations may probably be traced. In order to clearly explain my meaning and to illustrate it more fully, some remarks of my brothers, Dr. Astley and Professor George Gresswell, may, in the first place, be mentioned.

It may be said that all new formations, as instances of which the enchondromata may be taken, are characterised by the preponderance of cellular elements. These are, of course, variously modified. They may fibrillate, and, further, may be at length calcified; but very rarely, if ever, do they develop into the highest forms of tissue, the muscular and the nervous (Buhl). This latter fact is only to be expected, since the tissues of most important specialisation must necessarily be those which are produced, so to speak, with greatest difficulty. It is a familiar fact that all the tissues of organisms are to be regarded as having their origin in cells. Similarly, too, new formations in man and

Digitized by Google

animals are also traceable to the proliferation of cells. Necessarily, the cells become more or less modified so as to become almost, if not quite, indistinguishable from their parent cells. New formations of all varieties are, I hold, to be looked upon as reversionary in nature, and are clearly traceable to a remote ancestral condition, when the primary importance of cells as units not greatly modified, distinct and uncombined into aggregates or but imperfectly and incompletely combined, was far greater in the respect of individual power than it can be, where each cell is dependent on the activities of other units, with which it is combined as in the higher forms of life.

As illustrating my theory, let me briefly consider some points regarding the enchondromata. Enchondroma myxomatodes presents structural features such as are met with in the notochord of the vertebrate animals. The cells of some enchondromata are stellate, their processes uniting into a network. A like condition of cellular structure is met with in the Selachii, which may be regarded as the root forms of the vertebrates. Again, enchondromata are most common in the limbs, and especially in their distal extremities; and, since the original condition of the vertebrate limb is represented in the selachii as a multitude of cartilaginous rods arranged in a definite manner (the rods increasing in number towards the distal extremity of the pro-pterygium, the meso-pterygium, and the meta-pterygium), we are perhaps justified in looking upon these facts as showing to us homologous relationship. Corroboration is seen in the frequency with which cartilaginous bodies develop in connexion with certain joints of the limbs in man and animals. These bodies are either single or multiple, and they are of all sizes up to that of a small apple. Cruveilhier figures a number of rounded cartilaginous bodies in the elbow joint. Mr. Smith removed over 200 loose rounded cartilages from the knee joint of a man at St. Bartholomew's Hospital. He also operated on a woman, aged twenty-eight, who had for six years presented a tumour in the upper third of the right arm, immediately beneath the skin. The tumour was pyriform, tapering towards the axilla. It was three inches and a half long, and two inches in diameter at its thickest part. It was encapsuled, and within the capsule there were found one large mass of cartilage and twelve or more detached lobulated bits of cartilage. There were also similar detached nodules of cartilages in the axilla. The limbs, in fact, of the higher animals may have therefore dormant germs of the ancestral rods of cartilage; indeed, cartilage cells have been found in the synovial tufts of some joints. From such centres some of the above-mentioned cartilages had apparently developed. Supernumerary fingers have been referred to the multifid condition of the rays of the selachian fin. New formations of capillary vessels are generally congenital, and they are much commoner in the skin of the head and neck than elsewhere. These facts might suggest the possibility that they bear homologous relations to the vessels which develop about the epiblastic involutions lining the visceral arches of the lower vertebrata. Dr. D. A. Gresswell recently saw a nævus, the distribution of which seemed to afford some corroboration for such a speculation concerning the homology of nævi. It extended in a snake-like form down the right side of the neck; it was distinctly raised, and it passed with a tapering extremity into the external auditory meatus, down which it extended for a considerable distance.

It will be seen that the view which Dr. D. Astley Gresswell pointed out, and which we now wish to lay stress upon, is that one of the primary properties of cellular organisms was that of multiplying by processes of fission and gemmation. This characteristic, originally possessed by independent units, is still, in greater or less degree, a feature of those units which, when combined in various ways, make up the tissues and organs of higher forms of life. At times, and under special circumstances, which, in the present state of our knowledge, in many instances can only be roughly traced, this ancestral tendency of the cells to divide and multiply on their own account shows itself once more with something of its old vigour, and then new formations of various kinds result. When the bloodvessels are invaded by pathogenic micro-organisms, may it not be that, as previously pointed out, a kind of warfare, so to speak, goes on between the blood cells and the vegetal germs, and that when the latter gain the victory the man or the animal dies; whereas in cases where the blood-cells possess the power of strong resista[illegible] the sufferer also withstands the deadly effects of the foe? In some instances, then, the fertility of cells in the way of reproduction would be highly serviceable to the man or animal, while in others such power of multiplication is manifestly most destructive. Is it not a great question if we should not, in our investigations of disease, search most diligently into all those conditions which would enable us both to control and to facilitate the growth and multiplication of cells?

Louth, Lincolnshire.

CASE OF

OSTEOPHYTES OF THE ARACHNOID.

BY F. H. M. BURTON, M.S. DURH., M.R.C.S.,
SURGEON, ARMY MEDICAL STAFF.

ON Nov. 28th, 1886, W. R——, a private in the 1st Battalion of the Royal Welsh Fusiliers, aged twenty-seven, who had served for a period of six years and three months in India, was detained in the Bhamo Field Hospital, suffering from ague. During his service in Burmah he had been twice in hospital for simple continued fever, and in May was invalided to Darjeeling from Mandalay, returning to duty in Bhamo early in November.

On admission, the patient was treated with quinine and a saline diaphoretic. He remained in bed during the day, and at 6.30 P.M. took some beef-tea. At about 9.30 P.M. a comrade's attention was attracted by his loud breathing and attempts to vomit. When I saw him he was lying on his back. On speaking to him he appeared to follow me with his eyes, but was otherwise unconscious. His pupils acted to light, and the conjunctivæ were sensitive; the teeth were tightly clenched, the right forearm was flexed at the elbow, and the fingers flexed on the hand, the right arm, forearm, and hand all being in a state of tonic rigidity, and the left arm and both legs in a state of flaccidity; occasionally both arms were jerked up in a spasmodic manner. Temperature 101·4°; pulse regular and good; breathing slightly stertorous; skin perspiring profusely. He had vomited a little bilious fluid.

On the morning of Nov. 30th, at 7.15 A.M., when I again visited the patient, he was suffering from clonic convulsions

Drawing exact size of osteomata.

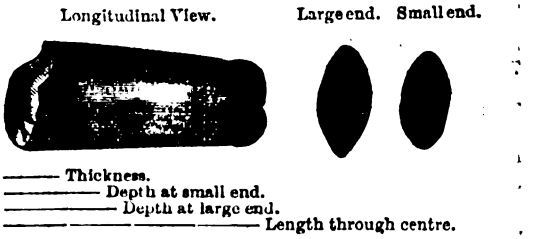
of the muscles of the head, neck, trunk, and arms; the right leg was affected at intervals. Temperature 101·6°; skin perspiring profusely; quite unconscious. The clonic convulsions lasted considerably over two hours, and became very violent, the head being drawn to the right; and once the man uttered a shrill cry when the convulsions were most violent. As nothing could be given by the mouth, an enema of bromide of potassium was administered. At 11.30 A.M. the convulsions had ceased, and the patient lay passive in bed. Temperature 107·4°; pupils contracted to the size of a pin's head and fixed; breathing stertorous; pulse irregular and rapid. The temperature afterwards fell to 106·6°, there was loud stertorous breathing, the pulsation gradually ceased, the pupils became dilated, seminal emission occurred, and death ensued at 2.15 P.M. The patient had been altogether fifty-three hours and thirty-five minutes under observation.

Necropsy.—General aspect of body: A well-nourished man, but decided malarial cachexia. Cadaveric rigidity well marked in lower extremities, passing off in the upper part of the body. Brain and membranes: On removing the skull-cap, some half-dozen small osteomata, from the size of a pea downwards, were found symmetrically arranged on either side of the groove for the superior longitudinal sinus, and growing as excrescences from the inner surface of the frontal bone, composed of compact bone (see accompanying drawings); owing to the close adhesions in this situation the dura mater was torn in taking off the skull-cap. After opening the superior longitudinal sinus from the cristi galli of the ethmoid to the torula Herophili, the falx cerebri were detached from the cristi galli, and the dura mater and the parietal layer of the arachnoid stripped off from before backwards. Immediately behind the fissure of Rolando of the left hemisphere, and over the

Digitized by Google

upper part of the ascending parietal convolution, the visceral and parietal layers of the arachnoid were strongly adherent; there was a small patch of freshly effused lymph on the pia mater, and flat osteophyte (made up of two pieces closely bound together side by side) of the size of the thumb-nail, one-seventh of an inch thick, growing from the arachnoid and pressing upon the brain, its under surface being very rough and having several spiculæ. An inch and a half in front of this growth was another three-quarters of an inch long, one-tenth of an inch thick, and one-fifth of an inch broad, with sharp needle-like extremities, curved downwards; this was situated at right angles to the falx cerebri. Between the two growths the membranes were much thickened and there were signs of old inflammation. A similar set of growths (three in number), in the same position as the first one described, were found growing in the arachnoid over the right hemisphere, but extending over about twice the surface occupied by those on the left hemisphere, and having several very sharp and needle-like spiculæ, all curved down on to the pia mater. The visceral and parietal layers of the arachnoid were adherent in the situation of the growths, as on the left side, but there was no sign of recent or active inflammation on this side of the brain. The upper surface of the dura mater was normal. There was no fluid in the subarachnoid space or ventricles of the brain, and no other signs of inflammation of the membranes or of the brain. The superficial veins of the right side of the brain were somewhat congested, and the right lateral, superior and inferior petrosal sinuses were full of dark tarry blood. Thoracic cavity: The right lung was firmly bound everywhere to the chest walls by old adhesions. There were some old tubercular deposit in the upper part of the pleura. The lung itself was œdematous, but otherwise healthy. The left lung was œdematous, and some old tubercular deposit existed in the upper part of the pleura; otherwise healthy. Heart normal. Abdominal cavity: Gall-bladder full of thick reddish bile. Spleen enlarged and soft. Pancreas normal. The stomach contained some ounces of thick bile, and the mucous membrane was covered with thick, stringy, sticky mucus. Duodenum full of thick bile. Jejunum normal. The ileum contained much bilious fæcal matter. Colon and rectum normal. Kidneys normal.

Remarks.—The growth of osteophytes from the arachnoid is a sufficiently rare pathological condition to justify the publication of the above case. There was no history of syphilis; there were no symptoms by which cerebral disease could be diagnosed till the fatal attack, when the symptoms of pressure on, and irritation of, the cortex of the left hemisphere of the brain were well marked. In my opinion the fever suffered from was malarial, and merely caused an exacerbation of the chronic disease, and determined the fatal irritation and inflammation.



Bhamo, Burmah.

FOREIGN BODY IN THE AIR PASSAGES.

By CHARLES BOYCE, M.B., C.M. EDIN.

THE following case is interesting as showing the length of time which a foreign body of the size shown by the accompanying diagrams may remain in the air passages without producing any untoward symptoms.

On October 20th last P. C ——, aged twenty, whilst driving home on a very dark night through a narrow lane smoking a briar pipe with a vulcanite mouthpiece was thrown out of his dogcart and rendered insensible, the pipe he was smoking being lost. For some time he lay insensible, and became cold and wet from the restoratives used by the surgeon who saw him at the time. When he recovered consciousness he was carried home and seen on the following day by my assistant, Mr. Macartney, and myself. His condition was as follows: There was considerable ecchymosis of the face and eyes, slight nasal catarrh, but no difficulty of breathing or impairment of expansion, resonance, or respiratory sounds, vesicular breathing being apparently equal over both lungs at repeated examinations. Examination of his throat showed nothing beyond relaxation of the fauces and elongation of the uvula. No laryngoscopic examination was made. There was no cough or shortness of breath; no pain or uneasiness, except on lying down in bed at night, when the breathing became whistling. This was the reason of my careful examination of the lungs, as I feared the development of some inflammatory trouble. As no improvement occurred in his condition, I advised him to go to Brighton for a change of air, cautioning him against going out at night or exposing himself to cold. When he had been some time there, one morning (Dec. 13th), whilst eating his breakfast, he swallowed a small fishbone, which caused a violent fit of coughing, during which he brought up part of the vulcanite mouthpiece of the pipe he was smoking at the time of the accident, the shape and exact size of which are figured in the dia-

grams. At the time of the convulsive cough a deep-seated pain at the sternal end of the right clavicle was experienced.

Remarks.—The most notable feature in this case was the absence of any serious symptoms; in fact, it was only whilst in the recumbent posture that any symptoms occurred pointing to the presence of a foreign body, and as the patient was quite unaware of what had happened to the mouthpiece of his pipe, the real condition was never suspected. I should be inclined to say that the foreign body lay crosswise in the trachea at its bifurcation, and that whenever he assumed the horizontal posture its position became slightly altered, so as to project more or less into the bronchi, causing the whistling breathing, and the pain at the right sterno-clavicular articulation which was felt at the time of its expulsion. Had it been in one of the bronchi, we should have expected far more serious symptoms from the size of the body, and the dyspnœa which was observed only on lying down would have been difficult to explain. The termination of the case was most fortunate for the patient, especially when we consider the size of the body expelled. Mr. Durham in Holmes' "System of Surgery" (3rd edition) gives the results of a number of cases of foreign bodies in the air passages, from which it appears that of those in which no operation was performed death resulted in about 40·94 per cent.

Maidstone.

OVARIAN TUMOUR FOLLOWING INJURY; OPERATION; RECOVERY.

By JAMES WILSON, M.D., F.R.C.S. ENG.

MISS L——, aged eighteen, gives the following history:—About three years ago she struck her left side against a door, felt faint, had severe and continuous pain for two years, and thought she could feel a lump at the seat of injury. About a year ago the swelling began to increase, with complete cessation of the pain. Bowels costive; menstruation irregular, periods varying from a fortnight to two months. She consulted a medical man, who treated her for indigestion and flatulence.

On examination the chest was found to be normal. Urine free from albumen. Slight œdema of feet and ankles. Family history of phthisis. Temperature normal; pulse 130 per minute. On examining the abdomen, it was found exceedingly enlarged, with distinct fulness on left side. On percussion, dulness extended from the pubes to the sternum. Resonance in flanks, but more marked on right side. Distinct wave of fluctuation in every direction. Per vaginam the uterus was normal, save that it was markedly depressed.

On March 3rd, under the A.C.E. mixture, ovariotomy was performed. The abdominal walls were thin, tense, and free from adipose tissue; hæmorrhage slight. On opening the abdomen the tumour was found to be non-adherent. It was tapped and about two gallons of fluid withdrawn, when a dense fibro-muscular tumour, weighing about 2½ lb., was removed with the cyst wall. The pedicle was tied with China silk. The other ovary was found enlarged and cystic, and was also removed. The abdomen was cleared of a little ascetic fluid with sponges. The abdominal wound was

Digitized by Google

stitched with silver wire, and iodoform powdered over the surface. No spray was used. The patient recovered from the anæsthetic in an hour after the operation. There was slight sickness, but no pain. Ice was given. Temperature 100° in the evening.

March 4th.—The patient has slight headache and pain. About two drachms of blood passed by Fallopian tubes. Natural sleep. The only unpleasant symptom was suppression of urine. Temperature 100·5°. Ordered milk, ice, and champagne in teaspoonful doses.—5th: Patient comfortable; temperature 99·2°, pulse 100. The napkin had a urinary odour.—6th: Patient slept well the previous night, and at 7 A.M. one pint of urine was drawn off by catheter. Wound healthy, and apparently healed. Temperature 99·2°.—7th: The patient has slight bladder irritation, and passes urine without the aid of the catheter. Temperature normal, pulse 98. Takes milk and champagne freely.

The case had an uninterrupted recovery, except that the bowels were obstinate, and there were severe griping pains for several hours on the eighth day. Three weeks after operation the patient was perfectly well, and able to move about freely.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

MIDDLESEX HOSPITAL.

THREE CASES OF SARCOMA COMMENCING IN CONNEXION WITH THE SCAPULA, THE THIGH, AND WITH THE FEMUR; RESULT.

(Under the care of Mr. J. W. HULKE.)

WHILST cancer (anatomically defined) is not often seen before the end of the third decade of life, sarcoma does not observe such restrictions, but attacks alike the young and persons in advanced age. But this statement is subject to the limitation that the melanotic variety rarely occurs before middle life, and glioma (regarded also as a variety of sarcoma) in its most frequent seat—the retina—has a strong predilection for infancy and early childhood. Youth and early adult life furnish a large proportion of cases of sarcoma originating in connexion with the motor apparatus, and under the circumstances incidental to these life-phases the disease usually runs a rapid course and manifests great malignancy. In the first and second of the following cases exarticulation at the shoulder and hip joints, ensuring a more complete removal of the tumour, would have offered a prospect of longer immunity from recurrence; but in neither instance would the patient accept this measure. The occurrence of secondary tumours within the skull, noticed in the third case, in which the primary tumour was in the thigh, is well illustrated by two preparations in the Middlesex Hospital museum taken at an interval of a couple of years from the same patient, a young adult: one a persistent sarcoma of the tibia, for which the leg was amputated; the other preparation a part of the brain, with five sarcomatous knots in the pia mater.

CASE 1. *Sarcoma originating in connexion with the structures attached to the coracoid process of the scapula; excision; recurrence; a second operation; some months later, death.*—In July, 1885, a milliner aged twenty-four, an anæmic blonde with flushed cheeks, was admitted for a swelling lying below the outer third of the left collar bone. It had a roughly hemispherical outline; its consistence was firm, yet elastic; it was evidently beneath the pectoralis major muscle: it was not attached to the clavicle or to the humerus; it moved with the scapula, with the coracoid process of which it appeared to be closely connected. No differences in respect of force, volume, and time were noticeable in the wrist pulses. No loss of muscular power and no impairment of sensibility of surface were observable in the limb. She complained of a dull aching pain in and about the swelling. The patient, a native of a northern county, said that she had been in London about a year, in the course of which her health, good before, had failed; she had become delicate, liable to faint, subject to palpitation and nervousness, and for the last three months had not menstruated. Nearly at the same time when her courses stopped, whilst washing before a mirror, she first noticed the swelling. A few days later she showed it to a doctor, who, regarding it as glandular, directed her to paint it with iodine. This had not, however, any curative effect; the swelling continued to enlarge, and then, pain supervening, she was advised to enter the hospital. The swelling was manifestly not of an inflammatory nature. There were not any grounds for considering it gummatous. Its rapid growth, its elasticity, its connexion apparently with bone, together with the woman's age, concurred in suggesting sarcoma. On July 20th the tumour was exposed by an incision following the interval between the pectoralis major and deltoid muscles. When the borders of these were retracted, it became apparent that whilst a small part of the tumour cropped out above the upper border of the pectoralis minor muscle, the chief mass of it was covered by this muscle. The latter was therefore divided; the axillary vessels, which were found displaced inwards by the mass, were drawn aside, and the deep connexions of the mass, which were found to be, as had been suspected previously, with the fibrous structures, attached to the coracoid process, being next divided, the removal of the mass was accomplished. The patient quickly recovered, and on Aug. 11th was able to be sent to a convalescent home in Sussex. When next seen, on Nov. 16th following, she complained of a slight uneasiness about the upper end of the scar, but nothing palpable was discoverable there. On Feb. 22nd, 1886, she returned, complaining then of severe pain in the shoulder and down the back and the inner side of the arm. A mass of some size could now be felt beneath the scar, but not implicating it, lying deeply beneath the axillary vessels, which it displaced inwards. The left radial pulse was weaker than the right. Two days later (Feb. 24th) the tumour was laid bare by an incision following the inner border of the scar. Its principal mass was found wedged in between the chest wall, the neck of the humerus, and the scapula. The axillary vessels and the brachial plexus ran through a groove in its anterior surface; the circumflex nerve pierced its substance. During the extrication of the axillary vessels and the nerve cords, a thin fascial capsule which enclosed the tumour was ruptured, which rendered the clean and entire removal of it less certain than it might otherwise have been. By March 15th the large wound had cicatrised, she left her bed, and by the 22nd appeared convalescent. She did not, however, recover strength, was low spirited, and she often complained of pain about the shoulder. On March 30th some hæmorrhage was detected in the neighbourhood of the coracoid process. She went for a few days into the country, and on her return on the 22nd of April a recurrence of the sarcoma was unmistakably present. A large ill-defined mass projected forwards the pectoralis major muscle, filled the armpit, extending thence upon the dorsal aspect of the scapula, and upon the back of the upper arm. She had much severe pain in the arm and in the shoulder, and she complained of some shortness of breath. The left side of the chest was now found less resonant and the respiratory sounds feebler than on the right side—changes which Dr. Cayley, who made this examination, regarded as suggestive of implications of lung by the new growth. This visceral implication placed the case beyond further surgical aid; she therefore returned home, where she lingered until the end of February of this year, death occurring about twenty-eight months after the first recognition of the swelling. Mr. R. Williams, the hospital pathologist, reported that the primary tumour and the recurrent mass both exhibited the fine structures characteristic of sarcoma.

CASE 2. *Sarcoma in the upper third of the thigh; excision; death from chest implication some months later.*—A bookseller's assistant, aged twenty-four years, was admitted into the hospital on Jan. 1st, 1884, with a swelling in the upper part of the front of the thigh, reaching very near to the groin, evidently involving the adductor muscles, and displacing outwards the superficial femoral vessels. Its figure was lobulated; its outline seemed definite. It was not fixed to the femur. He had been very active, and much addicted to football playing. For about eighteen months he had had pain in the thigh, which had been attributed to a sprain.

Digitized by Google

One doctor had told him it was due to muscular rheumatism, and another had pronounced it to be sciatica. About thirteen months after the first occurrence of pain the swelling appeared. Its increase had been rapid. The diagnosis was sarcoma. On May 7th the tumour was exposed by an incision nine inches long down the front of the thigh. The superficial femoral vessels were first disengaged; they ran in a groove in the outer aspect of the mass, and the separation of the vein was rendered difficult owing to the close adhesion of the paravenous connective tissue to the new growth. The saphena vein, the upper end of which near its termination was expanded into a large sinus, and also closely adherent to the tumour, was clamped with two pairs of pressure forceps and the intermediate adherent part excised. In the dissection required to liberate the deep aspect of the mass, it became evident that this was wedged in between the superficial and the deep femoral vessels. The tumour appeared to have begun in the adductor longus muscle. After its removal the deep femoral artery was seen exposed in nearly its entire course. The extensive and very irregular wound was washed out with a chloride of zinc solution (twenty grains to the ounce); two long and wide drainage tubes were inserted, and the edges brought together with silk sutures. Iodoform was freely applied. A compressive pad of boric-acid charpie with an outer gauze completed the dressing. All movement of the thigh was prevented by a Liston's long splint. The subsequent course was marked by absence of fever. By June 19th the large wound had quite closed, and a week later he left the hospital. The pathologist, Mr. R. Williams, reported the tumour to present the structure of sarcoma. The patient died at home in the following autumn of a chest affection, which the doctor in attendance said was due to the occurrence of tumours in the lungs.

CASE 3. *Sarcoma of the upper part of the thigh spreading into the pelvis; secondary tumours on and in the skull and orbit and in the lungs.*—On Aug. 26th, 1885, a clerk, aged twenty-five years, was admitted on account of an affection of the right thigh. The upper third of the thigh was very obviously swollen; its girth exceeded that of the left thigh by three inches. The swelling was caused by a deeply situated mass which implicated the upper part of the thigh bone. Below, it subsided so gradually that its limit in this direction could not be precisely defined. Above, its boundary was irregular. At the inner side of the thigh in the adductor region the mass appeared to be connected with the body and the symphysis of the os pubis, external to which it dipped beneath Poupart's ligament into the iliac fossa, forming there a rounded knob. Yet more externally it passed below the anterior superior iliac spine into the buttock, involving the gluteal muscles and concealing the great trochanter. Behind this last-named process was an old scar, as of a former abscess. The thigh was kept flexed on the trunk at about 80°. Flexion could be carried much further without discomfort, but extension gave pain and it caused rotation of the pelvis. The patient stated that in childhood he had been an in-patient under the care of the late Mr. C. De Morgan for hip disease; that he had recovered, retaining a useful limb, having fair mobility of the thigh; and that he had remained well until about eighteen months previously, when he began to suffer severe paroxysmal pain in the thigh, which he had himself attributed to a fall occurring some six months before. For some weeks he was treated for sciatica, without relief. The characters of the swelling, together with its history, were thought to indicate sarcoma, probably periosteal, originating in the femur. The extension of the new growth into the pelvis forbade exarticulation at the hip joint.

Indisposed to regard his condition as being beyond the aid of surgical operation, he left the hospital on Oct. 9th. One week later he was readmitted, being then much weaker and greatly worn by the increasing intensity of the pain in the swelling. This latter also had become larger. Three days later (Oct. 19th), on waking in the morning, he found the sight of the right eye imperfect, and his eyeball appeared to be very slightly more prominent than the left. A few days after this proptosis was unmistakably present. He lingered until Dec. 15th.

At the examination of the body, made on the following day, Mr. R. Williams found a large sarcomatous tumour embracing the upper part of the femur. It displaced but did not otherwise implicate the large femoral vessels. It involved the brim of the pelvis, and secondary masses were present upon the front of the lumbar part of the vertebral column. A single nodule of sarcoma was found in the base of each lung. A thin diffuse layer of sarcoma existed beneath the scalp over the apex of the lambdoidal suture, and two masses were present within the skull—one beneath that just mentioned, the other anterior to it in relation to the coronal suture. These intra-cranial masses apparently arose in the cerebral membranes; there was not any gross perforation of the bones of the vault of the skull, and by the unaided eye no continuity between the extra- and the intra-cranial masses was discernible. A nodule of sarcoma of the size of a walnut was discovered in the middle fossa of the skull, from which it passed into the orbit surrounding the optic nerve, and displacing forwards the eyeball.

NORWOOD COTTAGE HOSPITAL.

MULTILOCULAR OVARIAN TUMOUR, WITH UMBILICAL HERNIA, COMPLICATED WITH STRONG PELVIC ADHESION; RECOVERY.

(Under the care of Dr. JOHN H. GALTON.)

E. S——, aged fifty-four, was admitted on Nov. 29th, 1886. She had been married for twenty-five years; no children or pregnancy. No family history of tumours. Eight years ago she first noticed a swelling in the middle of the abdomen (umbilical hernia). Six months ago general swelling of the abdomen was first perceived. She has now a large ventral hernia just above the umbilicus, which is included in its walls. It measures fifty-two inches and a half round the hernial protrusion, and forty-nine inches and a half above it. Dulness and distinct fluctuation are present all over the abdomen, except in the right hypochondriac and umbilical regions, where it is resonant. On internal examination, there is a small fibroid on the anterior lip of the uterus, a large mass in front, and a smaller behind in the posterior uterine wall; slight coffee-coloured uterine discharge, not offensive. For the last six months she has been unable to keep down solid food.

On Dec. 2nd, at noon, chloroform was administered by Mr. S. Sidney-Turner, and Drs. Miller and Hetley and Messrs. Gandy and Plimmer assisted. The abdomen was opened by an incision five inches long below the hernial protrusion, through very thick and fat abdominal walls. On passing the hand into the abdomen upwards, some coils of intestine were found adherent to the cyst and forming the ventral hernia. On separating these, the cyst wall gave way, and some of the clear fluid contents were discharged into the abdomen and externally. The cyst was then tapped with Spencer Wells's trocar, and drawn gradually outside the abdomen, anterior omental adhesions being separated. After tapping several secondary cysts and freely opening them with scissors, the tumour was found to be held to the right brim of the pelvis by a strong and thick adhesion. This was torn through, upon which copious hæmorrhage immediately followed, filling up the pelvis and pouring out of the abdomen. A large sponge was firmly fixed upon the pelvic brim, the tumour drawn out, and the pedicle transfixed and tied with silk ligature. An adhesion on the posterior wall was then tied with catgut, two pieces of bleeding omentum were tied and cut away, and, after much difficulty, the vessel in the pelvic adhesion was secured and tied with silk. The uterus had a fibroid of the size of a walnut on the anterior wall, and another of the size of a mandarin orange on the posterior wall. The pelvis and peritoneum having been well sponged out, the wound was closed by four deep thick silver wire sutures and four superficial thin silver wire, and dressed with green protective and carbolic gauze, secured by strapping and flannel bandage over the whole. The quantity of fluid was five gallons, the weight of solid 3 lb. 4 oz. The operation lasted two hours, one of which was occupied in searching for the bleeding vessels. At 2 P.M. the pulse was 84, and the temperature 95·8°. She was ordered twenty minims of tincture of opium every three hours. At 8 P.M., pulse 104; temperature 96·8°; slight hiccough; ordered ice to suck.

Dec. 3rd.—Pulse 106; temperature 99°. In twenty-four hours nineteen ounces of urine were drawn off. Quite free from pain. At 12 o'clock the patient was ordered a teaspoonful of kreochyle every hour (she cannot take milk). At 8 P.M. the pulse was 110; temperature 100·4°. Has passed urine naturally once.

4th.—Pulse 104; temperature 100°. Passed a good night; no pain; the tincture of opium repeated every six hours.

Digitized by Google

Ordered a teaspoonful of kreochyle every two hours; beef-tea one ounce every two hours.—8 P.M.: Pulse 104; temperature 100·6°. Beef-tea causing nausea, the patient was ordered one drachm of an extract of beef, to alternate with the kreochyle.—3 P.M.: Passed flatus freely; urine thirty-five ounces in twenty-four hours.

5th.—Pulse 94; temperature 98·2°. Changed outer flannel bandage, as urine had been passed in sleep. Abdominal walls move freely in respiration.—8 P.M.: Pulse 100; temperature 100·8°. Passed forty-two ounces of urine in twenty-four hours.

6th.—Pulse 84; temperature 99°. Bowels acted freely under her. Ordered raw meat sandwiches and rice soft-boiled in beef-tea.—8 P.M.: Pulse 104; temperature 100·2°. Ordered one drachm of brandy every two hours. Passed thirty-five ounces of urine in twenty-four hours.

7th.—Pulse 84; temperature 98·2°. Was sick this morning after eating bread-and-butter. Ordered whiting, and one ounce of brandy every three hours. Dressed wound; all united; no discharge at any part. Good abdominal respiration, but much swelling (flatulent) at the upper and right side of the abdomen. Passed twenty-five ounces of urine in twenty-four hours.

8th.—Pulse 84; temperature 98·8°.—8 P.M.: Pulse 96; temperature 99·4°. Passed thirty ounces of urine in twenty-four hours.

9th.—Removed all deep and superficial sutures, applied strips of plaster, pad of dry lint and bandage. Passed thirty ounces of urine. Ordered fowl and ale.

From this time the progress was uninterruptedly good so far as the abdomen was concerned, but a troublesome bed-sore had formed. The slough separated on Dec. 19th, and disclosed a large and deep wound, which slowly healed, and she was discharged cured on Jan. 22nd, 1887.

Remarks.—One point of interest in the case was the resonance of the umbilical hernia mass with the dulness over all the rest of the abdomen. This was explained at the operation by the collapsed state of the afferent and efferent portion of the intestine which led to the coils in the sac. The strong adhesion of the back of the tumour to the pelvic brim did not admit of ligature before division, but the fact that it rested upon bony structure and not upon bowel admitted of its being torn forcibly, without other risk than the severe hæmorrhage which followed.

HERTFORD GENERAL INFIRMARY.

A CASE OF REMOVAL OF THE COCCYX; REMARKS.

(Under the care of Mr. WILLIAM ODELL.)

FOR the notes of the following case we are indebted to Mr. H. G. Shore, house-surgeon.

A housemaid, aged twenty, was admitted on March 3rd with the following history. Last July she fell and injured the bottom of her spine. She had also a second fall on the ice last December, and the coccyx was again injured. Since July she had felt pain at each catamenial period, but for the last five weeks the pain had been excessive and continuous when in the sitting position; there was also slight momentary pain on coughing. The pain and distress of late became so great that the patient begged to have the bone removed.

On examination per rectum, the coccyx was found to be bent at a right angle, in-curved, and pressing upon the rectum. It could be straightened at its lower part, but would not remain in position. On March 9th, the bowels having been previously freely relieved by a dose of castor oil, followed by an enema, the patient was placed on her left side and ether administered. An incision was then made from the end of the sacrum over the coccyx to its extremity, the parts being divided down to the bone, from which all ligamentous and muscular structures were then removed. The coccyx was separated at its junction with the sacrum, to which it had become ankylosed at an obtuse angle. There was rather copious hæmorrhage at one time during the operation, but it was controlled by applying sponges soaked in very hot water. A piece of gutta-percha tissue was put in for drainage, the wound closed with silver sutures, and dry boracic lint applied. In addition to the ankylosis with the sacrum—the result of previous fracture—the coccyx was found to be broken about an inch from its extremity, the lower part being freely movable. To avoid moving the dressing the urine was drawn off until the 11th, when the patient passed it herself by turning upon her face Half a drachm of laudanum was giv[illegible] night, and the bowels kept from acting until the 14th, when a dose of castor oil and a soap enema were given. The gutta-percha tissue was removed on the 13th and the sutures on the 15th. The wound healed almost by first intention; the patient made an uninterrupted recovery, and was discharged cured on April 7th.

Remarks by Mr. ODELL.—From the time of the operation until May 2nd the patient was entirely free from pain or even inconvenience when sitting, all the distressing symptoms which rendered the operation necessary had disappeared, and there was no pain or difficulty in defecation.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

The Relation of a certain form of Headache to the Excretion of Uric Acid.—Alcoholic Paralysis.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

Dr. ALEXANDER HAIG communicated a paper on the Relation of a certain form of Headache to the Excretion of Uric Acid. Previous papers by the author on the influence of diet in this headache, and its clinical relationship to gout, are referred to. An investigation of the urine was undertaken with a view of testing the relationship to gout. Meat and cheese were taken with the object of bringing on a headache, for purposes of experiment. The relation of this headache to the excretion of uric acid at first appeared equivocal, but definite results were obtained on separating the urine excreted *during* the headache from that before and after. There appears to be retention of uric acid before the headache, excessive excretion during the headache, and diminished excretion after the headache. The excess during balances the diminution before and after; there is no absolute excess of uric acid; hence the previous equivocal results. During a headache there is little or no alteration of the excretion of urea. The relation of the uric acid to the urea is important, and is greatly altered during the headache. When, as the result of *plus* exercise, there is a large excretion of urea and uric acid (though in their normal relation), headache is not far off; and if anything causes the uric acid excretion to fluctuate, headache will be present during its excess and absent during its diminution. This fluctuation in the excretion of uric acid does not affect the urea, is temporary and transient, and there is proof that urates may accumulate, while the kidneys are quite sound. The theory which best explains everything in this connexion is that of diminished alkalescence of the blood. Does gout consist in a diminished power of forming ammonia to neutralise acids, resulting in a permanent diminution of the alkalescence of the blood? The influence of meat diet and beer in this respect, and the well-known connexion of fourpenny ale with gouty deposits, are referred to. A dose of acid, either introduced from without or formed internally, may cause temporary retention of uric acid, and so lead to headache. Beer will do this. Retention possibly does not explain everything, as the excess during the headache appears to exceed the previous retention. There may be temporary excessive formation as well, hence the good effect of salicylate of soda, which diminishes the formation of uric acid. The good effect of a meal on this headache is due to the fact that it increases for a time the alkalescence of the blood. Hence also the good effects of a somewhat vegetarian diet and alkalies in its treatment. The relation here shown between the headache and the excretion of uric acid has an important bearing on the pathology of gout and other diseases connected with uric acid, in demonstrating the way in which temporary retentions of uric acid may be occasioned, and in supporting the theory of diminished alkalescence of the blood, as a cause of these retentions.—Mr. G. D. POLLOCK related his personal experience of headache. The urine passed during the attack was always pale and clear. Bilious vomiting used to terminate the attack. Calomel soon afforded relief.—Dr. CHEADLE congratulated Dr. Haig on his valuable paper. He doubted, however, whether irregular excretion of uric acid would explain all headaches. Women who were not large meat eaters suffered from this headache. After railway journeys or anything

Digitized by Google

causing vibrations the headache could hardly be due to faulty excretion of uric acid. He knew a boy who journeyed from Ireland to Eton and always had a prostrating headache, the result of this journey. The scent of strong flowers—e.g., hyacinth—also caused a headache. He (Dr. Cheadle) also suffered from megrim if for one hour he remained in an ill-ventilated room. A good dose of wine would sometimes cause megrim to disappear, and this seemed to militate against the views advanced.—Sir DYCE DUCKWORTH referred to the two classes of large eaters and drinkers, and those who could not eat or drink to excess without suffering soon from headache and other symptoms. This latter class had a smaller margin for the disposal of excess of food, and he supposed that Dr. Haig belonged to this class. He thought that the author deserved great credit for so painstaking an investigation.—Dr. PERCY KIDD was conscious of at least two sorts of headache: one for which no remedy is useful; the other brought on by obvious causes, and easily relieved by stimulants and other means.—Dr. WARD thought there were three sorts of headache, in his own experience. Tiny little chalk stones from the joints of the hands were obtained at the age of fourteen, when the real megrim began. The nervous headache was probably quite distinct in its causation from that which arises from inspecting a picture gallery or from excitement. This latter kind may be relieved by a dose of strychnine. Other headaches experienced by him were amenable to sal volatile. Bottled beer is less liable to cause headache, owing to the soda added. A specific gravity of 1030 was also noticed, followed by a copious deposit of urates. Sometimes a decided exaltation of spirits preceded the severe form of headache.—Dr. HINGSTON FOX inquired as to the method of estimating uric acid best adapted for clinical work.—Dr. HAIG had noticed the light colour of the urine, but this seemed to have no relation to the amount of uric acid. He explained his views of the relation of diminished alkalescence of the blood as causing a retention of uric acid.

Dr. DAVID W. FINLAY read a paper on three cases of Alcoholic Paralysis (multiple neuritis). The three patients, all married females, came under the care of the author in the Middlesex Hospital in the course of last year. The first case, E. F——, aged twenty-eight, a confirmed drunkard, had suffered from weakness in the knees for more than a year. To this succeeded difficulty of walking, and numbness in the hands and arms, soon followed by paralytic symptoms. In the hospital she lay helpless in bed with the legs flexed, rambled in her talk, and had delusions. The muscles of the arms and legs were much wasted, and she had double wrist drop and foot drop, with much pain on pressure or passive movement, and abolition of plantar and patellar reflexes. She had complete control over the bladder and rectum. Abundant large and small râles were heard over both lungs, and the epigastrium receded during inspiration. The liver was enlarged. On electrical examination the muscles of the legs and arms generally showed the reaction of degeneration. The optic discs were normal. She gradually got worse and died on the seventeenth day after admission. The urine was normal, and the temperature hectic throughout. Post mortem, the lungs were found to be the seat of tubercular disease, and the liver was large and fatty. On microscopic examination the cord and spinal roots were normal; all the nerves examined showed advanced degenerative changes, and the extensor carpi radialis longior muscle was crowded with connective tissue nuclei and round cells. The second case, M. J. P——, aged twenty-eight, had a history similar to the other, and the symptoms were much the same as regards the nervous system. There was less degenerative reaction, however, and less wasting. The temperature was seldom above normal. The liver was enlarged, but the lungs were not diseased. At the post-mortem examination the brain and its membranes appeared normal; the cord on section seemed somewhat atrophied in the grey matter, but no other change was noted. Under the microscope the cord did not present such a typically healthy appearance as in the former case. The greater number of the large cells in the anterior cornua were shrunken, the branching processes were less clearly defined, and many had dropped out of their places, leaving holes in the section; but the results were probably due to comparatively unsuccessful preparation. Most of the nerves examined showed changes similar to those found in the other case, but these were less strongly marked, except in the anterior tibial nerve. The spinal nerve roots were sound. The third case, E. C——, aged forty-three, resembled the other two as regards the history and many of the clinical phenomena, differing, however, in result, slowly progressive recovery having taken place. She has regained the use of her limbs, can now walk and dress herself without help, and has lost her delusions. The reflexes, however, have not yet returned, and her feet and legs have lately become œdematous. Reference was made generally to the clinical and pathological history of the disease, and particularly to the history of the individual cases as excluding the idea of causes other than alcoholism being concerned in the production of the symptoms. The frequent coexistence of tubercular disease was also discussed, and reference made to a recent paper by MM. Pitres and Vaillard in this connexion. The paper concluded with a few remarks upon the treatment of the case which had recovered. Microscopic specimens and drawings were shown.—Dr. HALE WHITE said that the cases bore out a clinical observation he had made, that the alcohol concentrated its action on one set of tissues, and those chiefly where the inflammation commences. The vessels were thickened secondary to perivascular changes. The change in the muscle was peculiar. In syphilitic and alcoholic neuritis he had observed no secondary influence on the skin. The bladder and the rectum were usually not affected, and this was rather to be surprised at.—Dr. HADDEN remarked on the legs being not very uncommonly in a state of flexion, and was glad to find this observation corroborated. Cutaneous hyperæsthesia was not marked, and as a rule he had not found tenderness of the nerves. Perforating ulcer, œdema, erythema, falling off of toe-nails, bullous eruption, and other trophic lesions he had observed in alcoholic paralysis. In five fatal cases he had examined the spinal cord was normal. In four there was phthisis also. Lancereaux had detected a slight sclerosis in the antero-lateral columns of the cord. The tendency to label all cases as alcoholic should be deprecated; other causes might cause the same grouping of symptoms.—Sir DYCE DUCKWORTH had had four cases in women during the last six months. The history of alcohol was not always easy to elicit. He had no doubt that alcohol did pick out certain tissues and act in certain lines. The condition of the muscular fibre was new to him. Muscular hyperæsthesia was to be observed, and he had noticed tenderness of the peripheral nerve trunks.—Dr. ORMEROD had noticed tenderness of the nerve trunks, and also one case at least of cutaneous tenderness. The muscular tenderness might be ascribed to an inflammatory condition. The infiltration of leucocytes could hardly be explained on the degenerative theory of the nervous changes. He had also observed the flexion of the legs. It would be important to have a guide to prognosis. The mental condition was an important point, was often characteristic, and might serve to differentiate cases of peripheral neuritis. The patient possessed great aptitude for giving circumstantial accounts of occurrences that have never happened. Mistaking the identity of places—e.g., supposing that the hospital was Newport Market—was also a feature in the mental condition.—Mr. JESSOP referred to the state of the optic nerves. If alcohol gives rise to amblyopia, these were the cases to investigate. The French ascribed the central scotoma to alcohol, and the English to nicotine. A case of central scotoma for red and green in a woman, who, however, smoked, was mentioned.—Dr. FINLAY said the vision was normal. The perineuritis might lead to degeneration by shrinkage of connective tissue, causing degeneration by pressure. He had satisfied himself that there was nerve tenderness.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A MEETING was held on May 6th, Dr. Alderson, President, in the chair.

Clinical Cases.—Mr. KEETLEY showed a case of Excision of Epithelioma of the Fauces, affecting the adjacent parts of the palate, tongue, and maxilla, with previous ligature of the external carotid; Mr. EDWARDS, a case of Recent Suture of the Patella; Mr. WAINWRIGHT, a case of Suture of the Patella; and Mr. DUNN, a case of an Albino.

Some of the Rarer Forms of Rectal Fistulæ.—Mr. EDWARDS read a paper upon this subject. He first drew attention to the difference of opinion existing between surgeons concerning the question of dealing with the sinus which extends upwards by the side of the bowel from the internal opening

Digitized by Google

of a complete fistula. He considered that the treatment should depend upon the position of the sinus to the muscular coat of the bowel; if submucous it should be laid open, but if submuscular it is better to leave it, thus avoiding the risk of incontinence due to division of the fibres of the internal sphincter. A cure may be looked for after the frequent injection of the sinus with tincture of iodine. After touching upon some of the more frequent errors in diagnosis and operative treatment, the author pointed out that there seemed to be a definite relation between the internal and external orifices of a fistula. For fistulæ having their external orifices situate behind a plane passing transversely through the centre of the anus usually have their internal aperture in the middle line dorsally, while those with their external orifice in front of this plane generally terminate in an internal opening immediately opposite, thus forming a simple, straight, complete fistula. The author then spoke of horseshoe fistulæ, which he defined as being a fistula with one or more external orifices on either side of the anus, with an internal one in the middle line behind. He said that not only were the descriptions of this form unsatisfactory, as found in most special works on the rectum, but the operative measures, when mentioned, left much to be desired. Surgeons of the present day when operating upon horseshoe fistulæ either slit up the sinus on both sides of the gut, thus dividing the sphincter in two places, or they content themselves with the division of one sinus, hoping that the other may heal of itself, with or without the insertion of a drainage-tube. The operation recommended in these cases, and for which the author said he had to thank his colleague and friend, Mr. Goodsall, was as follows:—Complete division of the sphincter in the middle line dorsally, laying open the abscess cavity and internal opening, and the subsequent slitting up of each lateral sinus from the external orifice to the central dorsal incision. By this means the whole of the fistulous track would be laid open and the sphincter would only suffer one division, and this in the most favourable manner—viz., at right angles to its fibres, thus avoiding all risk of subsequent incontinence, which so often happens after the operation as usually practised. In conclusion, the author related two interesting and rare cases: one of fistula completely encircling the bowel, and the other of fistula originating in the pelvi-rectal space—i.e., between the bowel and levator ani muscle.—Mr. WHITMORE referred to that form of incomplete internal fistula which was associated with phthisis, and remarked that rectal fistulæ should always be operated upon early.—Mr. KETTLEY related the case of a married lady from whom he removed a growth the size of a Spanish nut from the submucous tissue of the rectum; the operation was followed by a fistula, which was treated by division of the sphincter, and a complete cure resulted.—Mr. BENHAM narrated some cases of rectal fistulæ which he had treated with success by injecting carbolic (1 in 20) solution.—Mr. S. BENTON made some remarks upon the blind internal horseshoe fistula, which he said Mr. Edwards had not mentioned.—Mr. CHAPMAN had used pure carbolic successfully in three cases of rectal fistula.—Mr. EDWARDS, in reply, said that no reliance could be placed upon the cure of a case with carbolic injections. The experiment could be tried, but division of the sphincter was usually called for. In phthisis the patient derived benefit by having his rectal fistula operated upon.

Some Points in the Selection and Administration of Anæsthetics.—Dr. HEWITT read a paper upon this subject, and said that he wished to limit his remarks to the consideration of the following points:—1. The best method of administering nitrous oxide and ether, either in succession or in combination. 2. The prevention of vomiting during or after the administration of an anæsthetic. 3. The danger of inducing general anæsthesia in persons so suffering from obstructive dyspnœa. 4. The possibility of dangerous symptoms occurring from the administration of opium or morphine prior to chloroform, ether, or other anæsthetics. He exhibited an apparatus which he had used for three years in hospital and private practice. It consisted of a Clover's portable ether inhaler fitted with a special form of face-piece, and with a bag capable of holding two gallons of gas. By means of this apparatus any desired combination of nitrous oxide and ether could be given. The amount of gas in the bag was always sufficient, when administered with the face-piece shown, to anæsthetise a patient before gradually admixing the ether vapour; and the whole apparatus was portable and could be changed before entering the room in which the operation was to be performed. By means of this apparatus there was no sudden transition from nitrous oxide to ether as when face-pieces were changed during the administration. Vomiting could be prevented by rapid and deep anæsthesia. In a large number of cases he had given half a grain of cocaine in half an ounce of water shortly before the administration of an anæsthetic. This was done with the object of lessening the sensibility of the gastric mucous membrane. Vomiting after anæsthetics was best prevented by keeping the patient upon his side, and by moving him as little as possible. The danger of inducing anæsthetic sleep in persons suffering from obstructive dyspnœa was then considered. Patients in this condition were dependent for their existence upon an increased activity of their respiratory mechanism, and failure of respiration was very likely to ensue under chloroform or ether.—Mr. LLOYD showed an improvement in ether inhalers, which consisted in a bag of very fine indiarubber, the cost of which would be found to be so immaterial that one could be used for each patient anæsthetised. The bag would, of course, take the place of the ordinary bag as used at present, and would be destroyed after use; thus the ether apparatus could not become a source of infection by either the tubercle bacillus or any infectious disease.—Mr. DAVIS said that chloroform was the best anæsthetic in ovariotomy.—Mr. MACKINLAY remarked that he always insisted upon a patient being deeply under the influence of an anæsthetic before dividing the optic nerve in enucleation of the eyeball. Partial anæsthesia, he thought, was in such cases fraught with some danger.—Mr. ALDERTON related the case of a man who died under ether, who had been admitted for a small operation upon the mouth. He deprecated the custom of admitting patients into hospitals, and hurriedly operating upon them without preparing them.—Dr. HEWITT replied.

On the Association of Mitral Stenosis with Gout and Granular Kidneys.—Dr. G. N. PITT read a paper on this subject, upon which it was not possible for a discussion to take place, owing to the shortness of time.

Mr. DUNN showed the following pathological specimens: (1) Sarcoma of the Os Uteri; (2) Sarcoma of the Dura Mater; (3) A Kidney and adjacent parts, showing a large Extravasation of Blood into the Peri-renal Tissue of the Left Side.

Mr. BENTON showed a Pedunculated Growth removed from the rectum of a man forty-six years of age.

ACADEMY OF MEDICINE IN IRELAND.

Malignant Disease of the Stomach, &c.—Fibro-Sarcoma of the Orbit.—Trephining for Epilepsy.

AT the meeting of the Pathological Section held on March 11th,

The PRESIDENT showed specimens of Malignant Disease of the Stomach, Pancreas, Liver, Kidney, &c., taken from a young man aged twenty. The patient was admitted into Sir Patrick Dun's Hospital on Jan. 11th, and died on Jan. 22nd. Two years previously he was attacked with heartburn, retching and vomiting, and epigastric pain. At the post-mortem the stomach was found to be greatly distended; pylorus constricted, and its walls dense and white; a mass of new growth in edge of falciform ligament, and one or two nodules on the liver; walls of gall-bladder invaded by the neoplasm; cavity small, containing green mucus; cystic duct occluded; dense mass of new growth, involving stomach, pancreas, right kidney, &c., and extending back to the spine. Left kidney healthy on section; right kidney invaded by neoplasm; portal vein pervious; abdominal aorta constricted by surrounding mass of new growth; right upper surface of diaphragm studded with white nodules. An immense number of round, flattened nodules all over each lung, and also internally, radiating from root. Heart and pericardium normal.

Mr. SWANZY exhibited a Fibro-sarcoma, about the size of an ostrich's egg, which he had successfully removed from the orbit of a boy, aged eleven years, and which had a history of four years and a half. The eyeball had become dislocated upwards under the upper lid, by which it was completely covered, and sat on the top of the tumour, but retained its consensual motions to a slight extent, notwithstanding its very abnormal position. Owing to the presence of the tumour, the orbit had become much increased in size, measuring 7 cm. vertically, 6·5 cm. horizontally, and 4·5 cm.

Digitized by Google

in depth. The patient, who was exhibited, made a perfectly good recovery.

Mr. M'ARDLE read a paper on Sarcoma, detailing cases which showed the deterioration of the different tissues of the body, apparently as a result of the disease. He noticed in all his cases a great diminution of the red corpuscles of the blood, and a slow and incomplete coagulation of that fluid. In these cases he met with spontaneous fractures, and on examining the bones he found them brittle, and the red marrow in a state of fatty degeneration. In seeking an explanation of the decrease of red corpuscles in the blood, he concluded that the destruction of the red marrow of the bones led to a diminution of their manufacture. He explained the emaciation of the patient by the lessened oxygenating power of the blood, which, in some of the cases, looked like serum, so poor was it in corpuscles.

Mr. W. I. WHEELER gave a description of a Calvaria and Brain after Trephining for Epilepsy, and exhibited specimens.—Mr. STORY asked what was the use of trephining for epilepsy if the seat of the affection were, as Mr. Wheeler had said, the medulla oblongata or the pons. Epilepsy was interesting from an ophthalmic point of view. It was known that after epileptic seizures the patients frequently had either transitory or permanent affections of their field of vision, and it was a curious fact that these affections took the form of concentric limitations of the fields of vision of both eyes. It was well known to those present that when a patient suffered from a lesion at one side of the brain, whether caused by a tumour or otherwise, his visual apparatus was damaged, but the effect produced was that there was a loss by both eyes of one half of their field of vision, the halves lost corresponding to the visual centre on the side of the brain affected. But after epileptic seizures the limitation was concentric, though also affecting both sides; and the explanation of this which had been put forward assumed that the seat of the epilepsy was not in the medulla or the pons, but in the cortical centres.

Secondary Suture of Ulnar and Median Nerves.—Excision of the Knee Joint.

At the meeting of the Surgical Section held on March 18th, Mr. J. H. SCOTT read a paper on Nerve Suture. The subject was a young man, aged twenty-one. He sustained an injury to the palmar surface of right forearm, about an inch and a half above the wrist joint, by putting his hand through a plate of thick glass. The accident occurred four months prior to admission into the Adelaide Hospital. There was distinct evidence, from the condition of the hand, that the ulnar and median nerves had been completely divided, without any attempt at regeneration. On April 16th, 1886, eighteen weeks subsequent to the injury, the ulnar nerve was sutured, three catgut ligatures being introduced to bring the freshly-cut surfaces together. Five days after the operation sensation had markedly improved. The patient returned to the hospital in the following August, being desirous of having a similar operation performed on the median nerve, on account of the success of the former procedure. The median nerve was consequently sutured on Aug. 31st, almost ten months having elapsed since the injury. Three weeks after operation the patient could distinguish the touch of a pin's point anywhere in the area of distribution of the median nerve. Mr. Scott stated that the result so far has been very satisfactory, nutrition of parts becoming rapidly normal. Judging from present appearances, there is every hope that the hand will become perfectly restored to usefulness.—Sir WILLIAM STOKES recalled a similar operation by Mr. Wheelhouse of Leeds, who related the details at the meeting of the British Medical Association in Bath. A man, having fallen accidentally on the sharp edge of a scythe, sustained a deep wound on the back of the thigh, followed by paralysis both of motion and sensation. About eighteen months after the accident Mr. Wheelhouse cut down on the sciatic nerve, which he found completely divided, and brought the ends together by sutures. There had been extreme muscular atrophy; but after the operation the man was soon enabled to return to his ordinary avocation as a field labourer. Thus was proved the efficacy of the operation, despite the lapse of a long interval since the injury. Dr. Scott's case was a further illustration of the great importance of nerve suture.

Mr. W. THORNLEY STOKER read a paper on some Elements of Success in Excision of the Knee Joint. He considered that the results of excision of the knee had been too favourably stated, and that many cases recorded in their early history as having been cured, had later on shown a return of disease. Age had been over-estimated as an influence for good or evil in this operation. Three things were to be regarded as of superlative importance in the prospect of success in excision of the knee—(1) complete removal of all diseased structures; (2) relative permanence of dressing; and (3) thorough fixation of parts. With regard to the first, he laid great weight on the careful removal of diseased synovial membrane, the commonest seat of tubercular foci, and the most troublesome to extirpate. In speaking of the second, he dwelt on the necessity for all oozing to have ceased before the dressings were applied, and argued against the use of Esmarch's bandage. He advocated the use of dry dressings, and the performance of the first dressing two or three weeks subsequent to operation. Speaking of the third point, Mr. Stoker recommended the use of Dr. Heron Watson's splint as modified by Mr. Thomson, and opposed the use of plaster-of-Paris as a retentive apparatus. He described the method of "dowelling" which he had devised as a means of securing the bones, and which he had found most satisfactory.—Sir WILLIAM STOKES said the plan of fixation of the bones devised by Mr. Thornley Stoker should be welcomed by every operating surgeon as superior to any other method of bone suture. Speaking of dowelling from the experience of his cases, he negatived the production of irritation or of suppuration in the part operated on.—Mr. FRANKS, taking *seriatim* the three points raised in Mr. Stoker's paper, said, with regard to the first, he concurred as to the removal of the synovial membrane, failure being mainly due to leaving foci of disease either therein or in the tissues round the joint. As to the second, the dry dressings were of inestimable value in keeping the part at rest without the discomfort of repeated dressings. He himself provided drainage by turning in little tongues of skin at the angles of the wound and stitching them to the back part of the soft tissues, without leaving any foreign body in the wound except the silver wires. As to the third point, he employed the dowels in one case, which afterwards failed from other causes. At the same time, the dowels kept the bones in good apposition, and brought about satisfactory union. Still, while the fixation of the bones was satisfactory, he was not prepared to say that the dowels were better than the wire sutures.—Mr. Croly, Mr. Lentaigne, Dr. Kennedy, and Mr. Thomson also spoke.

Prevention and Treatment of Disease.—Latent Typhoid Fever fatal through Cardiac Thrombosis.

At a meeting of the Medical Section held on March 25th, Dr. C. F. KNIGHT read a note on the Prevention and Treatment of Disease. A fever may abort at any time—spontaneously or by the administration of therapeutic agents. Acute articular rheumatism may be treated by one of seven plans—viz., alkaline, quino-alkaline, mint-water, salicylic acid and salts, salicin, chalybeate, and eclectic. Advantages of alkaline treatment: First, rapidity of action; second, absence of cardiac complications; third, rapid defervescence. Quinine, an antipyretic and antiseptic, must be given with greater regularity, and in sufficient doses to produce satisfactory results. A tolerance may exist. In 1883 the author gave the largest quantity of quinine ever recorded to one patient—viz., in twenty-four hours, 131·25 grains; five grains subsequently produced cinchonism. Temperature analogous to septicæmia. Quinine may fail to reduce temperature; alkalies rarely do. The author believes that mint-water, salicylic acid and salts, and salicin influence the disease, because they are antiseptics. Cases where rheumatoid fibro-ankylosis of vertebræ and joints exists are well treated with small doses of salicylate of sodium, assisted by massage. As to the pathology of acute articular rheumatism and other diseases, the manifestations may be due to organisms in the blood, which are destroyed by antiseptics, and cannot live in a strongly alkaline medium. Source of organisms: 1. Outer world, through ingesta, or by gases inhaled. 2. May arise in digestive or respiratory tract, as by germs introduced, or coalescence of organisms, which separately are innocuous. Do normal digestive ferments ever give rise to morbid processes? Means of combating disease, dietetic, hygienic, and therapeutic; farinaceous food causes a rise in temperature in febrile affections. Therapeutic agents to include—1. Abortives. 2. Inhalation of gases. 3. Antiseptics, as turpentine, in acute croupous pneumonia. 4. Rectal in-

Digitized by Google

flations of medicated vapours, which was advocated as a means of combating disease, fevers, phthisis, and cholera in 1873. 5. Atomised liquids, a spray of a solution of cuchlorine, cooling and grateful in fevers, and where thirst is a prominent symptom. The best abortive for diphtheria, croup, mumps, and the exanthemata is red iodide of mercury, prescribed in hospital in these diseases since the commencement of 1884; dose, one-sixteenth of a grain thrice daily in the form of pilules, first dose a double one. Children bear this treatment well. In adults it may cause colic; if so, allay with an opiate, which increases action of mercurial. Opportunity for trying this treatment now offers in the present epidemic of scarlatina. The author requests physicians to adopt this plan, and to communicate the results of their observations to the Academy.—The PRESIDENT expressed his dissent from Dr. Knight's views as to the superiority of the alkaline over the salicylate treatment of acute rheumatism, and drew attention to the fact that some patients in rheumatic fever continue to suffer from the pains, no matter what drug is administered, until milk is excluded from their dietary.—Dr. KNIGHT, in reply, urged the desirability of resorting to therapeutic agents, which appeared to act as abortives, instead of trusting solely to isolation. There was a distinction between salicylic acid and salicylate of soda, and he spoke of cases treated with the acid and not the salt.

Dr. A. MONTGOMERY read a case, communicated by Surgeon-Major R. HARMAN, A.M.S., of latent Typhoid Fever, which proved suddenly fatal without the disease having been recognised during life. The patient, a dragoon of splendid physique, aged forty, was admitted to hospital for slight eczema of the left leg, which readily yielded to treatment. He never complained of any symptoms, abdominal or otherwise, except a slight cough, for which the usual remedies were applied; the temperature was taken on several occasions, both morning and evening, without finding any rise above normal. However, on the sixteenth day from his admission, after being up and about as usual, he vomited about a pint of fluid resembling coffee grounds, and expired immediately afterwards, being quite conscious and free from pain to the last. A post-mortem made three hours after death revealed a dense fibrinous clot, of a pale amber colour, occupying the right auricle and ventricle, firmly adherent to the endocardium and tricuspid valves, and extending into the vena cava and pulmonary artery. The parietal and visceral peritoneum was covered with thick masses of recent lymph, and the peritoneal cavity contained about two pints of semi-purulent serum. Just above the ileo-cæcal valve, the ileum, on the anterior free surface of the bowel, presented an oval open gangrenous ulceration, about three inches in length and half the circumference of the bowel in breadth, destroying all the coats of the bowel; and although opening freely into the peritoneal cavity, there was no extravasation of the intestinal contents. There was another gangrenous patch about six inches higher up, and Peyer's patches exhibited every stage of the disease.—Dr. FINNY said the case brought forward by Surgeon-Major Harman was one of great interest and rarity. In enteric fever, until the post-mortem examination was made, it was difficult, if not impossible at times, to give an accurate diagnosis, and sometimes during life the ulcerating process may advance unnoticed until marked by a gush of hæmorrhage. The present case revealed an interesting clinical fact, that the patient had marked pathological lesions of several hours', if not days', duration, without having presented any subjective symptoms. There was no evidence that death was caused either by thrombus of the heart or embolus of the pulmonary arteries. The action of the peritoneal inflammation, as it became developed, produced weakness in an already fatty heart; and the clot found in the right ventricle was really the result of a failing heart in the death agony, and not the cause of death.—Dr. JOHN WILLIAM MOORE concurred in the conclusion that the pathological appearances in the intestine were those of enteric fever.—Dr. DUFFEY said that his reading of the case was that death was due to simple collapse, the result of perforation of the intestine—a view which was borne out by the history of the case. There was nothing in the lung to suggest that death should be attributed to pulmonary thrombosis. Cardiac thrombosis was an uncommonly rare lesion.—Dr. KNIGHT said the case presented the characteristics of general septicæmia, of which enteric fever might be regarded as a variety; but the enlargement of the viscera and the intestinal ulceration did not constitute sufficient evidence of its being one of true septicæmia. In gynæcological cases adhesions were found without any history of severe attacks of pain or serious inconvenience to health.—The PRESIDENT said that he considered this case one of typhoid fever, but it was rare indeed to have such a normal temperature and an entire absence of severe symptoms before the fatal termination.—Surgeon-Major HARMAN, in reply, said the temperature was taken by the ward master, an intelligent non-commissioned officer, about a dozen times, by means of the ordinary clinical thermometer, in the axilla, and it was never above 99°. There was softening of the mesenteric glands. The clot found in the heart was of a pale colour, and firmly adherent to the endocardium.

MIDLAND MEDICAL SOCIETY.

A MEETING was held on April 13th, Mr. Lloyd Owen F.R.C.S.I., President, in the chair.

Talipes Calcaneus.—Mr. EDWARD FREER showed two cases of Talipes Calcaneus that he had treated by tenotomy at the Orthopædic Hospital. The section was made obliquely, and the tendon sutured by kangaroo-tail tendon, as suggested by Mr. Walsham. The results in both cases had been highly satisfactory, no signs of relapse having occurred after a period of six months from the operation. This was performed with antiseptic precautions, the feet being extended to their utmost and retained there by plaster and an anterior interrupted splint. Mr. Freer pointed out the necessity of ascertaining before operating whether there was sufficient nerve power in the paralysed limb to prevent a recurrence, and also the advantages of galvanism and massage for some time after.

Ruptured Brachial Plexus.—Mr. MORRISON showed a man, aged forty-six, who was admitted into the General Hospital, under Mr. Bartleet, on Dec. 27th last. He had fallen a distance of forty feet upon some loose bricks, and had sustained fracture of the right upper ribs, right clavicle, and lower jaw, together with rupture of the brachial plexus, and probably laceration of the inner coats of the axillary artery, on the same side, with occlusion of the vessel. There was emphysema of the chest wall, neck, and right upper limb as low as the wrist. For about ten days he remained in a critical condition, with collapse of the right lung, bronchitis, and delirium; but eventually he convalesced and became an out-patient; the upper limb, however, remaining paralysed, both as regards motion and sensation in the area of distribution of the brachial plexus. The limited movements that remain appear to be imparted by the trapezium. Anæsthesia of the limb is complete, excepting in the part supplied by the intercosto-humeral, descending branches of the cervical plexus, and possibly also by some filaments of the circumflex. Pulsation in the axillary artery ceases abruptly below the clavicle. The right pupil has remained persistently smaller than the left, indicating lesion of the sympathetic in the neck. Massage and galvanism are being used to the limb.

Dr. SUCKLING showed a woman aged forty, who presented the appearances of Myxœdema in a typical form. He also introduced a patient who had been successfully treated by trephining for Jacksonian Epilepsy. Dr. Suckling also exhibited a number of Sphygmograms.

Mr. JOHN TAYLOR read a paper based on a series of twenty-three consecutive cases of Abdominal Section.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

A MEETING was held on Friday, April 15th, Mr. Hatherly, President, in the chair.

Dr. HANDFORD showed the following cases:—Neuritis of the Ulnar Nerve following typhoid fever; Empyema in a man aged forty-one, cured by opening and drainage; Aneurysm of the Arch of the Aorta, with Paralysis of Left Vocal Cord, in a man aged forty-three; Aneurysm of the Arch of the Aorta, with Paralysis of Left Vocal Cord, in a man aged fifty-six.

Dr. HANDFORD also showed a case of Aneurysm of the Aorta for Dr. Ransom.

Mr. ANDERSON reported a case of Bullet Wound of the Brain, and showed the specimen.

The PRESIDENT read a paper on Infant Feeding for Dr. Marshall.

Reviews and Notices of Books.

A Text-book of Medicine for Students and Practitioners. By Dr. ADOLF STRÜMPELL. Translated from the Second and Third German editions by HERMAN F. VICKERY, A.B., M.D., and PHILIP COOMBS KNAPP, A.M., M.D., with Editorial Notes by FREDERICK C. SHATTUCK, A.M., M.D. London: H. K. Lewis.

THE readiness with which our American *confrères* undertake the translation of the best German works deserves to be widely recognised. Had it not been for their enterprise and devotion many such writings would have remained practically unknown to the English practitioner, who has derived so much instruction from their perusal. One involuntarily calls to mind the work of Niemeyer, which on its first appearance fascinated the medical world. There was a thoroughness of treatment and a freshness of style about that book which could not fail to impress the reader, and which gave the work a widespread popularity; but text-books are apt to fall behind the times, and require in these rapidly progressive days to be constantly renewed and re-edited if they are to retain their popularity; and they are apt to lose their original uniformity and spontaneity of expression by being refurbished at the hands of others. If only therefore as an exposition of modern medicine from the heart of "young Germany," we should welcome this edition of Dr. Strümpell's admirable text-book. Its publication will, however, increase considerably the difficulties of choice before teachers and students by adding another text-book upon medicine of high merit to those already in existence.

So far as it has been possible for us to judge, Dr. Strümpell's work will bear favourable comparison with others of the same class. It is not the mere compilation of an industrious student, but it bears ample evidence of the independent observation and thought which add so much to the force of an author's teaching. The author, too, is already well known in clinical medicine. His contributions to neurology are widely known and acknowledged, and this fact must render the chapters in the present work dealing with diseases of the nervous system especially valuable. They form, indeed, an admirable treatise in themselves, covering a wide field in a masterly manner. Nevertheless, Dr. Strümpell shows that his attention has not been wholly engaged by this department. The rest of the work is written with as much evidence of personal knowledge as that dealing with diseases of the nervous system. That he is thoroughly imbued with the importance of modern researches into the etiology of disease is evident in the chapters which deal with the acute specifics. "The cause of typhoid fever must be sought," he says, "in some specific organised pathogenetic poison," and he considers that the bacillus discovered by Koch and Eberth is apparently that poison; erysipelas is "a disease of the skin excited by the presence of a specific pathogenetic micrococcus" (p. 57). "Beyond a doubt the diphtheritic poison is organised" (p. 62); but the difficulties of its isolation are admitted, and the proof of its presence is said to be as yet inconclusive. Even more dogmatic is the following statement with respect to cholera, which would hardly be subscribed to by Dr. Klein. Dr. Strümpell says (p. 73): "Some time ago it had become evident that the real cause of cholera consists in the infection of the system by a specific micro-organism. Koch was, however, the first to succeed in the search for the poisonous agent"; and after giving Koch's views upon the comma bacillus, he goes on to say, "These statements have been since confirmed by all competent investigators, while the various alleged refutations of Koch's results have all proved erroneous." These extracts suffice to show the spirit in which the author writes, and there is something to be said for the adoption of clearly defined views upon the etiology of specific diseases such as are afforded by bacteriology. An English author would, however, have expressed himself more cautiously—though perhaps not to more advantage in imparting clear ideas to the student. The fact is that upon this vast question of etiology we have arrived at a period when opinions and facts are strangely commingled, and we have to break away from old ideas before we can place ourselves in a position to assimilate the new.

The system employed in the description of diseases is orderly, and the arrangement of facts is good. It is a novel, but decidedly beneficial, departure to find the symptomatology of such a disease as typhoid fever, for instance, described side by side with descriptions of the anatomical lesions. Some of the subjects also are introduced by chapters giving a general survey of the anatomical and physiological facts underlying the morbid conditions subsequently dealt with—a plan which is followed to the fullest extent in the section of diseases of the nervous system.

We have little doubt that this work will be favourably received in this country, as it has been in Germany, where within a few years it has run through three editions. Its value has been decidedly enhanced by the pains taken by the editor, Dr. Shattuck, who has made several additions—particularly in the subject of "Treatment," and elsewhere—that contribute to its completeness. The translation has been well executed, and the book produced in a single well-printed volume. We have no hesitation in recommending it to students; whilst there must be many practitioners who will be glad to have the opportunity of becoming familiar, through its pages, with the present standpoint of scientific medicine.

Nervous Diseases and their Diagnosis. By H. C. WOOD, M.D., LL.D. Philadelphia: J. B. Lippincott and Co. 1887.

Diagnosis of Diseases of the Nervous System. By C. W. SUCKLING, M.D., M.R.C.P. London: H. K. Lewis. 1887.

NOTWITHSTANDING the abundance of works and books on diseases of the nervous system, we think that good reasons may be found in both the present books to justify their existence. The chief excellency of Dr. Wood's book is its suggestiveness, and of Dr. Suckling's its conciseness. We shall illustrate our remarks in commenting on the books before us by selecting for special treatment one subject in each, taken not at random, but as fairly representing the general character of each work.

Dr. Wood is perhaps best known in this country for his work on Chorea, and we shall examine his article thereon. The first statement is not one to which we can attach any importance: Acute general chorea is usually due to St. Vitus's dance. Whatever is, is. In the definition of St. Vitus's dance, Dr. Wood says "there is often a distinct loss of muscular power." Our own way of writing this sentence would be, "there is always loss of power of volitional movements." Dr. Wood thinks enough evidence may be adduced to prove the existence of reflex chorea. In our belief, in most cases of "reflex" chorea the special irritant—e.g., intestinal worms—is but one of many causes of the chorea, the main cause being the irritable state of the motor centres. We concur in the statement that "an acute chorea may be intimately associated with minute cerebral embolism, and also with other lesions of the brain, among which lesions may be especially mentioned the peculiar alteration of the ganglionic cells of the brain, noted by Meynert as pervading the whole organ in a case of chorea." At the same time, we cannot but think that chorea may coexist with defects in the "motor" cells, without these being recognisable by any means of research at present known to us. Indeed, a page or two further on Dr. Wood clearly states the case. Chorea of pregnancy, hysterical

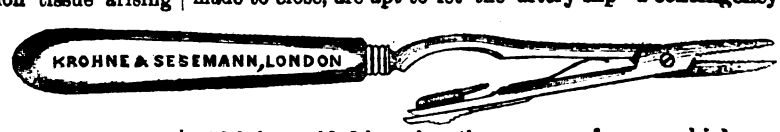
Digitized by Google

chorea, electric chorea, rhythmical spasms, local choreas, chorea of stumps, chorea in internal inflammations, and habit choreas are other varieties recognised by Dr. Wood, and it is in thus boldly naming various varieties that we see the suggestiveness which is the leading feature of the book. We cannot, however, agree with all that the author states under these various headings, and are inclined to think that his shots are often wide of the mark. For example, we can see no striking analogy between the chorea that may accompany internal inflammations and that twitching which goes by the name of paramyoclonus multiplex. Our recommendation of Dr. Wood's book cannot be to students, but to those who have already acquanted themselves with neurology it will doubtless afford much interest and some instruction.

Our selection from Dr. Suckling's book is the chapter on Diseases of the Peripheral Nerves, consisting of thirty-one pages, and there is a great deal of information imparted in this brief space. "Qualitative electrical changes are always present in severe cases, the faradaic response being lost and the reaction of degeneration present," is not sufficiently clearly put for a student to understand; it would have been better to say that qualitative electrical changes are always present in well-marked cases, the reaction to faradaism being diminished or lost, the reaction of degeneration being usually present (see p. 144). Bearing in mind that we look for faults as well as excellences, we cannot but object to the looseness of such an expression as the "myeline and axis cylinders being broken up" (p. 263), though we may admit that in the space occupied a better description could scarcely be expected. But the truth is, we look in vain for ground for any serious criticism of Dr. Suckling's little book, and we feel bound to give it the warmest reception; our only doubt about its fulfilling all the demands likely to be made upon it by the student or practitioner is that it may not be so clear and lucid to them as it is to neurologists, for of course one versed in any subject is apt to see more in a simple statement than another who has no previous knowledge of it. To students and practitioners who have read other works this production will prove extremely valuable in time of need: to the former just before examination; to the latter in every-day practice.

Tumeurs de l'Ombilic. Par le Dr. FRANCIS VILLAR, Ancien Interne des Hôpitaux de Paris. Avec 7 Photogravures. Paris: J. B. Baillière et Fils. 1886.

CRITICS of specialism and its abuses have often prophesied that some day a surgeon would rise up and take the umbilicus under his special care, and devote all his energies to the treatment of the maladies, real and imaginary, of this square inch of the human frame. The essay before us shows that such a forecast was by no means an impossible exaggeration. Dr. Villar has written a very interesting account of the tumours of the umbilical cicatrix, excluding hernia, and anyone who will read it will be likely to admit that his time has not been misspent. The classification of these tumours is simple and useful. The distinctions between the two kinds of fungous tumours or polyps of the umbilicus met with in infants are clearly drawn. The commoner variety is a mass of granulation tissue arising subsequently to and in connexion with the separation of the cord—a lobulated growth, secreting pus, sometimes curable by caustics, and not containing any special structure. The rarer form is an adenoma, a truly congenital growth developed from the omphalo-mesenteric duct, discharging mucus, and being very thickly studded with tubular glands—a growth only to be cured by excision. Cases of dermoid and sebaceous cysts, of fibroma, papilloma, myxoma, and sarcoma—all of them very rare—are recorded, and a large part of the essay is devoted to a study of cancer. It is shown that primary cancer of the umbilicus is nearly always epithelioma, while secondary cancer is as commonly carcinoma. The primary form has a marked tendency to invade the peritoneum and spread in a mushroom-like mass over the inner surface of the abdominal wall. On the other hand, carcinoma of the abdominal wall or of any of the abdominal viscera has a special tendency to infect the umbilicus, so that in any case of cancer of the umbilicus other malignant growths should always be looked for. These and many other interesting and important facts, together with details of diagnosis and treatment, are well discussed, and a bibliography completes the whole. Like many of his countrymen, Dr. Villar is not well acquainted with the medical literature of this country, from which he could have collected additional cases and observations.



The Asclepiad. No. 14, Vol. IV.

DR. RICHARDSON, writing on the phenomena of Palpitation, with and without intermittency of the Heart and Circulation, believes that all persons who suffer from intermittent pulse have occasional attacks of palpitation, but that some persons have palpitation who are not liable to ntermittent action. Speaking of the causes of palpitation, Dr. Richardson thinks that "the worst mischief of all is the practice of carrying to bed the anxieties and annoyances of the labours of the day." He believes that more than half the cases of palpitation of the heart occur from this one mistaken and foolish practice. The practice is, we grant, foolish and mistaken, but it should not be forgotten that the practice itself may be due to disorder of the chief organ of mind. The clinical aspects and relations of palpitation and intermittency, as studied with the sphygmograph and cardiograph, are dealt with in a very interesting manner. The article on Winter Palaces of Health and Camps of Health at Home forms the subject of some editorial observations on another page of our present issue. "John Arbuthnott, M.D., F.R.S., the Medical Scholar," is the subject of the biography and portrait—an autotype from an oil painting by Jervas, in the possession of the Royal College of Physicians. The fac-simile autograph of John Arbuthnott has been reproduced from the Register of St. Andrews University, where it was inscribed on Sept. 11th, 1696. This number contains the third chapter on "Practical Biometry, or the Measurement of Life in Health and Disease," and treats of the relationship to insurance of life. If we cannot altogether subscribe to the distinctions drawn by Dr. Richardson, we can at least admire his originality in making classes according to particular external characteristics: (*a*) the atheromatous, (*b*) the alcoholic, (*c*) the arcus senilis expressions. The fourth chapter deals with the various temperaments in relation to the measurement of life for insurance.

New Inventions.

BRYANT'S TORSION FORCEPS.

ALMOST any kind of artery forceps may be used for twisting the end of an artery, whether it be spring forceps provided with a spring catch or sliding bolt, or pressure forceps with the usual scissors handle. The spring forceps, however, in whatever manner they may be made to close, are apt to let the artery slip—a contingency which is avoided in using the pressure forceps, which are made on the principle of a lever. The latter, however, owing to the scissors-shaped handle, are not convenient for twisting. By the direction of Mr. Bryant, Messrs. Krohne and Sesemann, of Duke-street, Manchester-square, have constructed for him the forceps (of which the accompanying woodcut is an illustration) on the lever principle, to which a handle is centrally attached. At the end of the lever is placed a bolt, which is readily governed by the thumb for opening and closing the forceps. The handle permits of easy rotation.

THE LANCET.

LONDON: SATURDAY, MAY 28, 1887.

WE regret that the committee which was appointed by the General Medical Council to consider the best methods of increasing the practical element in medical education should have made a report without taking any evidence from practitioners, pupils, and teachers. If some further time and consideration had been devoted thereto, we are sure that the report would have been more complete and satisfactory, and would have had greater weight with the profession than it can now have. The question of pupilage with a general practitioner is far too important to be dismissed with the mere opinion that the advantage to be derived from personal instruction was of too great value to be altogether sacrificed: an opinion held, without doubt we should suppose, by every member in the profession, and which reads as a truism so obvious that it was surely almost unnecessary to solemnly record it in a report. But what does the committee suggest for its being carried into practical effect? A term of six months spent in personal pupilage is suggested, not necessarily six consecutive months, but six in all, and that the six months should be taken during the long vacation, and after the examinations in anatomy and physiology have been passed. Such a suggestion as this is so very crude that, if a little more consideration had been bestowed upon it, it would never have been put into a report from so important a body as a committee of the General Medical Council. Pupilage is worth something or it is not. If worth nothing, let it pass away, as it is now doing throughout England; it has never existed to any great extent in Scotland. But if it secures a something of importance in medical education, surely the suggestion of six months in long vacations being devoted to it is insufficient. Personal instruction in "the routine of medical life and its accessories" is valuable in proportion to the earliness of the time in the pupil's education that it has taken place. It is the moulding and forming of habits, manners, and modes of observation and thought that should be secured by such routine, as well as the knowledge of common diseases and their treatment, and these must be secured early or not at all. Pupilage, to mean anything of value, must mean a pupilage of at least a year under a practitioner's guidance and tuition, and that year must be the first year of medical study; and this is distinctly recognised by the Royal College of Surgeons of England, which permits a student to begin his professional education as a pupil of a legally qualified surgeon holding the appointment of surgeon to a hospital, general dispensary, or union workhouse, or where such opportunities of practical instruction are afforded as shall be satisfactory to the Council. The only objection to an imperative instead of a permissible pupilage is that it must lengthen the time devoted to professional education, and so increase its cost; for we cannot seriously take into consideration as a worthy substitute six odd months in vacations in the latter half of the student's curriculum. Moreover, he only gets two long vacations between his second and his final examinations; and if he is, as he should be at this time, a clinical clerk or dresser to in-patients, he will probably get a freedom from his duties for only a week or ten days consecutively; for hospitals know no long vacations, and even visiting physicians and surgeons must find their substitutes when they take their month's holiday. If a student can afford an extra year, it can be well spent with a good general practitioner, who has patients among all classes, and this is the best way, perhaps, of commencing a professional education; but, at the same time, a knowledge of chemistry, physics, and more especially of the biological sciences, must be secured. These are very important parts of the medical curriculum, and may, along with a routine knowledge of common diseases and their usual remedies, be acquired early.

IN the last number of the *Asclepiad* Dr. B. W. RICHARDSON advocates a great national effort for establishing in our own islands a system of Winter Palaces of Health and of Camps of Health at home. The first part of the idea is not new, for he proposed it in 1865, in a memoir which he then wrote on the Medical History of Bath, but he now adds another suggestion for utilising the high grounds of the country into what he calls "Camps of Health." The argument in favour of this new project is stated in a very simple manner. The library of the writer, a room eighteen feet square, has been kept, he tells us, during the whole of the past winter well ventilated at all times with fresh air warmed to 64° F. What can be thus effected on a small scale can be extended to any required degree; it is all a mere matter of engineering skill, the details of which are well understood and easily mastered. His proposal is to extend the plan by erecting in suitable localities a series of palatial residences which shall include, in a closed square, magnificent grounds covered in with glass, and fitted with playgrounds, tennis courts, subtropical gardens, and everything that can contribute to the health and pleasure of the invalids who require a resort from inclement seasons in a genial and summer climate at their own doors. The proportions are supplied for one of these Palaces of Health on a minor scale, so as to afford one hundred residences in fifty substantially built houses of two storeys surrounding a square of gardens and grounds accessible by four grand entrances. Each of the houses, divided into an upper and a lower flat, would be sixty feet deep from the front, twenty-five feet wide, and fitted with every convenience for the residence of an invalid, with every room and part at an equable and adjustable temperature. The two sets of residences would accommodate at least one hundred invalids comfortably and luxuriantly, with their attendants and friends. On the roofs would be four galleries or terraces, covered in glass and laid out with flowers, each gallery twenty yards wide and about one hundred yards long, in all a promenade of nearly a quarter of a mile. The square, covered at a great height with an arch of glass, like the Crystal Palace, would be the inner garden, kept always at an equable temperature, and arranged for exercises of every kind suitable for the sick. Add to the whole a library, a reading-room, a lecture-room, a concert-room or

Digitized by Google

theatre, a gymnasium, the most approved baths, including the Turkish bath and the swimming-bath, with a pump-room at which the different artificial or imported mineral waters could be obtained, and it must indeed be a fastidious invalid who could not for health's sake spend the months of December, January, February, March, and April in such a Palace of Health. In this palace it is urged there need be no monotony, nor one whit less of good exercise, than is obtainable at foreign resorts, while the immense advantage would be secured of entire freedom from treacherous winds, and the other accidents of atmospheric variability which the best climate within easy reach of Great Britain fails altogether to secure. How these advantages are to be had is next considered, and it is contended that in the palaces foreshadowed, we could in these days "command climate." In such a palace we could make our own electric suns to shine, if we wished them, by night as well as by day; we could filter the air from every kind of impurity, and by the effect of electric discharges set at defiance fog, cloud, and storm. By the same means we could make the air what we pleased in respect to its physical influence on the life of man and on vegetation. We might even utilise an east wind for the value of the oxygen it contains, whilst we might take out of it its fatal sting, and turn it into any quality of wind we liked so soon as it had entered our territory. We might make it dry or moist, keen or soft, bracing or relaxing, as we wished.

Dr. RICHARDSON still suggests that Bath is the centre in which this advancement should first be established. The climate and position generally are favourable to the experiment, and the history of the city as a health city is very commendable; but most important of all is the flood of heated water from the springs, which now flows away into the Avon, and which would be priceless as a means of helping to sustain the summer climate of the Winter Palace and Garden of Health. There are, however, many other sites in England, in Scotland, and in Ireland, in which Palaces of Health could be constructed on a much grander scale; sites in which valleys of great extent ready for roofing, if we may so say, and for being laid out in a vast expanse into Winter Palaces, wait only the hand of man "to become in all their natural beauties gardens of perpetual summer, with miles of park verdure and pleasance." For Camps of Health at high levels, Dr. RICHARDSON suggests the utilisation of certain of the old Roman encampments which form such striking points in the history of our country. These, he shows, are ready for immediate transference into his design. Into this matter we cannot now enter, but we offer the idea generally as a "practicable ideal" for our readers to con over. It would afford good work for the profession were it realised; but, above all, it would, as its proposer says, be patriotic in its bearing, by encouraging native labour, creating a wholesome diversion, and inaugurating a new era of national progress.

WE have already referred to the means at the disposal of the General Medical Council for maintaining the standard of proficiency to be required from candidates at qualifying examinations, and we pointed out that the Medical Act of 1886 requires the Council to appoint inspectors of examinations for those bodies which were before the passing of the Act legally qualified to grant diplomas in respect of medicine and surgery, or which have since entered into combination with other bodies for this purpose. We stated, moreover, that when, in the absence of such combination, the Council has appointed assistant examiners, these examiners were required to secure at the examinations the maintenance of such standard of proficiency in medicine, surgery, and midwifery as is required from candidates at qualifying examinations. As yet the Council have only appointed examiners in surgery to assist the Society of Apothecaries, and presumably they intend to send to the examinations of the Society the inspectors in medicine and midwifery whom they have recently appointed; it remains, however, a matter of grave doubt whether they have fully complied with the intentions of the Act in adopting this course. The point will probably not be raised at the present time, but it would become of much importance if the Council were at any time to receive from their inspectors a report that the examinations were insufficient. If the Council are satisfied with the accuracy of this report, they must of necessity communicate their views to the Privy Council, who are empowered to deprive the examining body of its right to conduct further qualifying examinations. The question would then undoubtedly be raised whether the Medical Council had themselves fully exercised the powers they possess for securing the maintenance of a standard of proficiency. It is lamentable that the position assumed by the Royal Colleges has created another complete qualification in London; it is some satisfaction, however, to observe that the undesirable element of cheapness will not be held out by the Society of Apothecaries as an inducement to candidates. The Society propose to apply to Parliament for power to increase their fees on the ground that the sum which might be an adequate payment for a licence in one part of the profession was inadequate for a licence in all parts of the profession. The granting of the licence of the Society will therefore we trust, be independent of competition based upon pecuniary considerations. The future alone can show whether the alliance of the Society with the Medical Council will sufficiently enhance the value of the qualification to make it acceptable to the profession.

The appointment of committees, which finally engaged the attention of the Council, gives rise to matter for comment. In their constitution sufficient regard has not been had for the relative population of the profession in the three kingdoms. Both in the Finance and Education Committees England only shares equally with Ireland and with Scotland; and, again, in the strengthening of the Executive Committee an Irish and Scotch representative only were added. The proportion of direct representatives assigned to the three countries must be regarded as some indication of the relative influence which it was intended should be exercised by the different countries in the work of the Council, and certainly in the constitution of the committees England has, therefore, been left somewhat at a disadvantage.

The delay in the publication of the Medical Register was the subject of some discussion at the close of the session. The early appearance of the volume is undoubtedly very desirable, but it deserves to be stated that there is no room for criticism of those who are engaged in its compilation. It is, indeed, but right that we should refer to the

Digitized by Google

ndebtedness of the profession to the Registrar, Mr. W. J. C. MILLER, whose admirable services have contributed in a large legree to the efficiency of the work of the Council.

THE progress made in hygienic researches by the application of bacteriological methods has been nowhere better exemplified than in the investigation of air. Dr. PERCY FRANKLAND has pursued the subject in this country with much profit, and there has lately appeared in the Philosophical Transactions a paper by Professor CARNELLEY, Mr. HALDANE, and Dr. ANDERSON of Dundee, which should be carefully studied by sanitarians. The investigations here described consisted in the analysis of the air of dwellings as regards carbonic acid, organic matter, and micro-organisms, the carbonic acid being estimated by the method of PETTENKOFER, the organic matter by that of CARNELLEY and MACKIE, and the micro-organisms by that of HESSE. As regards dwellings, their inquiry involved a comparison between houses of from one to four rooms and upwards, and the composition of the air within these tenements with that without. As an example we may cite from one of the numerous tables the following figures, which represent the average quantities in one-roomed houses, relatively to those in houses of four rooms and upwards (which are taken as 1): cubic space per person, 0·11; carbonic acid, 2·0; organic matter, 4·4; micro-organisms, 6·7 (bacteria 6·9, moulds 3·0). The carbonic acid, organic matter, and micro-organisms all diminish in quantity as the cubic space per person increases from 100 to about 1000 cubic feet; but beyond this capacity there is a slight increase in these impurities, which is attributed to inadequate ventilation of the larger rooms. An instructive comparison is made of mortality statistics with the composition of the air of these dwellings—the death-rate increasing in proportion to the rise in impurity of the air, there being a very rapid increase in the death-rate among young children, and the mean age at death being very greatly lessened. The death-rate from phthisis is lower in those living in one- and two-roomed houses than in those living in three rooms, but this anomaly is readily explained when the early mortality of the former from other diseases is considered. Thus the death-rate per 10,000 from (1) diarrhœa, acute bronchitis, broncho-pneumonia, and meningitis is—for dwellers in four rooms and upwards 19·6, for those in three rooms 27·6, for those in two rooms 39·7, and those in one room 59·8; from (2) phthisis the rates are respectively 13·0, 27·6, 24·4, and 14·6. The inquiry also showed the effect of impure air in promoting pulmonary disease; and as regards infectious disease the mortality from measles and whooping-cough seemed distinctly connected with the class of house, whilst, contrary to expectation, no such relation held for diphtheria. The memoir also enters fully into the subject of the composition of the air of schools, of mills and factories, and of the Royal Infirmary, Dundee, and proves that the determination of carbonic acid alone is not a sufficient indication of the purity of a sample of air. We can only mention the very exhaustive study of the conditions which influence the excess of organic matter and micro-organisms, and the proofs of the superiority of mechanical over natural ventilation, but may state that the authors give as "standards of purity" the occurrence of 10 vols. of carbonic acid per 10,000 in the air of dwelling rooms, and of 13 vols. per 10,000 in that of schools—or an excess over outside air of 6 vols. in the one case, and 9 vols. in the other. These limits should not be exceeded. Nor should the excess of organic matter within the house over that of the air outside be equivalent to more than 2 vols. oxygen per 1,000,000; and the excess of micro-organisms should not be more than 20 per litre. Of these three classes of impurities, the carbonic acid (in the amounts mostly present) is the least deleterious to health, being compensated for by increased frequency of respirations; but the "organic matter" probably has a great effect in lessening the health and predisposing to disease; whilst micro-organisms, apart from specific infection, may be responsible for broncho-pneumonia, so frequent and fatal a complication of the prevalent bronchial catarrh and other affections. The paper concludes with suggestions of remedies—especially the adoption of mechanical ventilation in the Board schools of Dundee, and improved ventilation by means of open grated windows in landings in block tenements; other recommendations, such as the avoidance of keeping lamps burning at night, the adoption of cleanliness, attention to frequent renewal of air as of more importance than the size of the rooms, and the construction of windows so that they can be freely opened at intervals to allow a good current of air to be sent through the rooms, are such as will commend themselves to everyone.

WE drew attention in our issue of April 30th to the question of the dissemination of infection through the agency of rags, as it has been met with in the United States. In this country the subject has been fully dealt with in the reports of the Medical Officer of the Local Government Board. The report for 1881 contained an account by Dr. PARSONS on the influence of cotton and linen rags in this respect, and there is now issued in pamphlet form[1] an account of the danger of such dissemination by means of woollen rags. These rags come mostly from abroad, being mainly landed at the ports of Goole, Hull, London, and Liverpool, and they largely find their way to the "shoddy" manufacturer, by whom they are ultimately used for weaving into cloth or into "linseys." Pure woollen rags, unless dyed, undergo no process which can be held with certainty to destroy infection; but rags of mixed cotton and wool are exposed either to sulphuric acid, or are treated in a stove in an atmosphere of hydrochloric acid gas in such a way that the cotton fibre is destroyed. But no real trust, as regards disinfection, can be placed in these methods of dealing with the rags. In the process of flock-making various kinds of woollen rags and carpets with a backing of hemp are used. At times exceptionally filthy rags stained with blood and excrement are used, and in some cases hardly any attempt at cleansing or purification is resorted to. On the other hand, an attempt has been made to deal with them effectually by disinfection under steam pressure. Inquiry on a wide scale as to the possibility of mischief resulting to those engaged in the various processes of manufacture to which these rags are subjected brings out certain valuable information. In the first place, the occupation, like others of a dusty character, was found to affect some workers so generally that the illness they suffered from acquired

[1] Eyre and Spottiswoode, East Harding-street, E.C.; A. and C. Black, Edinburgh; Hodges, Figgis, and Co., Dublin.

Digitized by Google

the definite name of "flock fever." But infection seems rarely to have been brought about. A few cases of small-pox amongst those who had been handling woollen rags in the making of "shoddy" were heard of, but Dr. PARSONS referring to the common belief that woollen articles are more likely to retain infection than cotton or linen ones, shows that this does not apply to the processes of manufacture of these several classes of rags; whereas it is well known how commonly calico rag sorters at paper mills are affected with small-pox. Indeed, the latter articles in the form of sheets and underclothing come into closer contact with the bodies than woollen articles, &c., and are hence more likely to receive infection; and it is the sorters of white rags for the best class of writing papers that suffer most. Still, certain cases of infectious disease were heard of amongst woollen rag sorters, upholsterers, and users of rag waste as manure, which were believed to be due to retained infection in the rags. The precautions suggested are as follows: Every rag-worker should be efficiently vaccinated and revaccinated. Avoidance of dust should be aimed at, especially in the direction of improved cleanliness and ventilation of premises. A moist heat of some 220° F. should be applied to the rags. This process should preferably be carried out in the bale, and the best methods of effecting it have been fully indicated in Dr. PARSONS's report on methods of disinfection in a recent report of the Medical Officer of the Local Government Board.

Annotations.

"Ne quid nimis."

A TEACHING UNIVERSITY IN LONDON.

IT is evident, from the activity displayed by the various bodies affected by the movement in favour of establishing a Teaching University in London, that the crisis in its history is not far off. The Special Committees of the Senate and Convocation of the University of London have recently met and exchanged their views on the proposed reconstitution scheme, so that we shall soon expect to see Convocation summoned for its discussion. Many of the graduates will strongly oppose the formation of Faculties composed of representatives of affiliated colleges, and, even should they be unsuccessful in their resistance, the powers of these Faculties are so limited that they cannot satisfy those who think that teachers should have practical control in a university. The scheme may not be passed by Convocation, or, if passed, it will only make some minor, but in our opinion necessary, changes in the University. It solves neither the general university question for the metropolis nor the special one of degrees for average medical students, as in other centres of medical education. The proposals of the Association for promoting a Teaching University for London must find greater favour with those interested in metropolitan education. A university which aims at providing for the student in all the subjects included in its Faculties the best attainable teaching, with the necessary aids and appliances, which requires attendance on a definite course of teaching as a necessary preliminary to graduation, and which secures to the teacher a direct and adequate representation in its councils and share in its administration, cannot fail to enlist the sympathy of the teachers in the metropolis. University and King's Colleges have now formally agreed by their Councils to petition for powers to form (with any other efficient college in the metropolis) such a university on the lines of the Victoria University, and we understand that, as a result of this decision at University College on the 21st, Lord Kimberley has resigned the office of President of the College. Lord Kimberley is also a member of the Senate of the University of London, and had therefore to choose between his University and his College. Powers will be asked to grant degrees in the Faculties of Arts, Science, and Medicine, and to add other Faculties. The difficulties of the medical degrees question are referred to in the petition, and a union with the Royal Colleges of Physicians and Surgeons of England, with a due recognition of the medical schools of London, is suggested as the proper means for overcoming these difficulties. Meanwhile, the Royal Colleges are engaged in preparing a charter and petition, asking for powers to grant degrees in Medicine only, and have declined to pay any attention to those who deprecate the severance of professional degrees from general academic influences, and think that the conferring of degrees should only be undertaken by a real university. Certainly the present time seems favourable, by a judicious combination and a little mutual forbearance, for the formation of a true metropolitan university.

EXTREME FREQUENCY OF PULSE AFTER PARACENTESIS.

AN interesting case in which extreme frequency of the pulse followed puncture of the abdomen for ascites, is reported and discussed in the *St. Petersburger Medicinische Wochenschrift* by Professor Dehio of Dorpat. The patient was a man aged fifty-six, with cirrhosis of the liver. In addition to a considerable degree of ascites, there was general œdema and an old-standing hernia, but no heart mischief could be detected, and the pulse was 86, regular, and of moderate tension. Immediately after the operation the man felt better and was able to breathe more easily, and a slight rise of the pulse was then noted. The next day the face was pallid, and the patient complained of giddiness and prostration. The radial pulse had become 162, thready, and weaker; the second sound of the heart could scarcely be heard. This condition continued without any great alteration for five days, the pulse rate varying from 180 to 150. No rise of temperature occurred, and the respiration was about 24. At Professor Kobert's suggestion two milligrammes of coronilin were introduced subcutaneously, which was shortly followed by a reduction of the pulse rate to 80. A few hours later, however, it rose again to 182. The next day, without any repetition of the coronilin, and indeed without any assignable cause, the pulse sank to 84, and did not again rise to any remarkable extent. From this time, however, the patient's general condition became worse, and he died eighteen days later. The necropsy showed fatty degeneration of the heart and general diffused arterio-sclerosis. There was some hæmorrhagic pachymeningitis and a good deal of clear fluid in the ventricles of the brain, the cerebral substance being of moderate consistence, without any softening and containing less blood than usual. The cerebellum and medulla were in the same condition. The cause of the extreme frequency of the pulse was evidently not the disease of the heart and vessels, as this still existed at the time of death, or eighteen days after the pulse had resumed its normal rate. It must be looked for in the anæmia of the medulla, which doubtless followed the operation. Dr. Dehio proceeds to discuss the question whether this anæmia affected the heart by stimulating the accelerator (sympathetic) centre or by paralysing the inhibitory (vagus) centre, and strongly inclines to take the latter view, quoting Nothnagel, who, in a recent article, says that when an extreme frequency of pulse is found associated with regularity of the intervals between the beats, a weak cardiac impulse, and an absence of other symptoms, or the existence of such as point to an incomplete emptying of the ventricles

Digitized by Google

paralysis of the inhibitory apparatus is indicated. Exactly these conditions existed in this case, as shown by its history and the sphygmograms obtained, which were of a hyperdicrotic type. Traube has also described a case of this rare condition. An old man, with phthisis, was unable to sit up in bed from the extreme frequency of pulse produced by the anæmia which the upright posture caused in the medulla, which, according to Traube, induced paralysis of the inhibitory apparatus, "the action of which is more easily suspended than that of the respiratory and vaso-motor centres." Another reason given by Dr. Dehio for the view he takes is that it is hardly possible that stimulation of the accelerator apparatus should have been kept up for so many days without any sign of the centre becoming fatigued, the interval between the pulse beats not having altered at all. The fact was that when the abdomen began to refill the medulla became engorged with blood and the vagus resumed its proper functions. Nothnagel has pointed out the analogy between the sudden loss of regulating power of the vagus, and the sudden loss of consciousness in epilepsy and fainting which is produced by very slight interference with the blood distribution.

HOSPITAL WEEK OF THE JUBILEE YEAR.

THE mere list of speakers who have promised to take part in the public meetings is enough to show how deep is the interest taken in Hospital Sunday. These meetings will be held in various parts of the metropolis. The speakers include Sir Wm. Plowden, K.C.S.I., Mr. Spurgeon, the Bishop of London, Sir Andrew Clark, the Lord Mayor, the Prime Minister, Rev. Dr. Allon, Mr. Henry Irving, the Duke of Argyll, the Duke of Westminster, Mr. Richard Chamberlain, the Dean of Westminster, Cardinal Manning, Lord Randolph Churchill, the Duke of Cambridge, and the Rev. G. S. Reaney. A cause which can command advocates so varied and so distinguished should have great success. The list of places at which the meetings are proposed to be held, with the proposed date and hour of the meeting, will be duly advertised. We urge upon all our readers to do their part to make the meetings effective. When the Prime Minister of England can steal half an hour from his toils to plead the cause of hospitals, and when some of the busiest men in the city can find time to organise such a set of meetings, it is the least that any benevolently disposed person can do to aid in every possible way to make them a success. Many fear that the Jubilee year will interfere with this great collection. This is to pay a poor compliment to the Jubilee, which can have no worthier memorial than the doubling of the sum usually raised for hospitals on Hospital Sunday.

POLYMORPHISM OF THE FUNGUS OF THRUSH.

CULTIVATED in gelatine, M. Audry finds that the fungus of thrush gives rise, at the end of five or six days, to a large number of small secondary masses, white and mammillated, in juxtaposition to the original growth introduced. On agar-agar at a higher temperature the vegetation is more rapid, but the mammillated aspect is less obvious. The multiplication is still more rapid when glycerised agar is employed, and on potato its growth is also successful. In these various cultivations no spores were found, but cells of oval form, of greater or less dimensions, arranged in a chain, in the angles of which secondary cellules may arise in mycelial expansions, altogether similar to yeasts. But sown in bouillon these organisms turn the liquid turbid at the end of two or three days, and a sediment of whitish flakes, consisting of agglomerations and mycelium of cellules—the true oidium albicans,—is found. In wine the mycelial growth flourishes; an acid medium favours their multiplication, which borax prevents. The form of bacterium aceti has not been discovered in these cultures. Thus the pathogenic organism of Muguet develops in two different fashions. In liquid bouillon it throws out profusely mycelial expansions, and is in the heyday of its vigour; it is then a saccharomyces. In a solid medium, on the other hand, it retains its condition of an oidium, being but slightly different from certain fungi; in this state it may be regarded as the spore of which the mycelium has remained in an embryonic state.

PENSIONS TO MEDICAL MEN AND THEIR WIDOWS.

ALL men should insure their lives early. All medical men especially should do so: first, because they should set a good example; secondly, because their lives are a little more precarious than other men's lives. But for all men early life insurance is a good thing. It implies some forethought. It can be done for a moderate sum, and it is a thing well over. We confess to something like shame at the frequent recurrence of painful cases of want of foresight and forethought in medical men who have allowed themselves to live and die without making any provision for those whom they leave behind,—apparently content that they should appeal *in formâ pauperis* to the pity of those who have their own burdens to bear and their own families to provide for. There is something almost mean in this conduct, especially in days when it is comparatively easy to make some provision. It is not for us to indicate or select the particular method. Medical men in London and the neighbourhood are almost without excuse in this matter with the Widows and Orphans Fund to subscribe to. For others there are the multifarious systems of the different offices for life insurance, some of them on very easy and favourable terms. Lastly, there is what is called the Non-forfeiture system advocated by Mr. E. C. Garland of Yeovil, and worked by the Edinburgh Life Office, by which by a certain annual payment a man may receive a certain sum at sixty or at death; and by which, further, in the event of his ceasing to pay premiums at any age, he will still, it appears, receive at sixty a larger sum than he has paid in premiums. Particulars of this system may be obtained in any individual case by application to the secretary, Edinburgh Life Office, 11, King William-street, E.C. But we repeat our contention, that a man who is living contentedly without having made provision for his family in the event of his death is acting discreditably.

MURDER OR HOMICIDE.

THE practice of criminal abortion is a kind of villainy the enormity of which we have no wish to minimise. To take away the life of an undeveloped infant, unless it be to save the more important life of the mother, is in itself an inexcusable piece of wickedness. To risk the mother's safety in doing so clearly aggravates the crime, and there are circumstances in which such an offence may even be regarded as murder. It is rather, however, in most cases, one of those misdeeds which lie just on the borderland between homicide and murder, and its exact significance must often be difficult to define. In a case recently tried at Warwick Assizes two persons were sentenced to death, though with a recommendation to mercy, for having caused the death of a young woman by procuring abortion. Here the evidence available seems to have amounted to proof of murder; yet it is, we confess, somewhat difficult for us to reconcile our ideas to such a supposition. Murder implies either a design to kill or the employment against the person of means capable of killing, with a reckless disregard of their worst possible effects. It is, we should say, virtually impossible that two persons desirous of hushing up a scandal by causing abortion should directly contrive the death of a third, the subject of this operation. When we come to the question of reckless procedure, the mere fact of the operation undoubtedly goes far to prove a criminal dis-

Digitized by Google

regard of consequences, and is in itself highly illegal. Nevertheless, we have still considerable difficulty in accepting the view that this in itself is enough to prove a graver crime than culpable homicide. It is at least doubtful whether some concession should not in such cases be allowed to the criminal on the ground that, while doing wrong, he has blundered through unskilfulness beyond his intention, or even his apprehensions. He goes about his malpractices, it is true, with his eyes open both to its dangers and its illegality, yet he must in his own interest endeavour to prevent the worst consequences. These are, as a rule, not impossible of prevention, whatever the uncertainty and difficulty of arriving at such a result. If it were otherwise, induction of abortion in any case would be impossible. Consequently, the abortionist, bad though he is, must in many cases be excused from such utter recklessness as would render him distinctly guilty of murder. We should remember, too, that the subject of his unscrupulous attempt is usually a consenting party, not a mere victim. These considerations have, doubtless, weighed with the jury in recommending the prisoners above mentioned to mercy; and, though we do not know of any injustice in the sentence, we are disposed to think that they may very fairly be urged as a plea for its commutation.

PATHOGENY OF GASTRIC ULCER.

THE precise pathogeny of chronic ulcer of the stomach is one of those undetermined questions which have led to considerable speculation, with comparatively little profit. The position, form, and nature of the ulcer have done more than any positive demonstration of the vascular lesion to favour the current doctrine of its dependence on arterial blocking. But everyone knows the difficulties in the acceptance of this view, not the least being the comparative frequency of the disease in the female sex, and the great preponderance of cases where the ulcer is solitary and seated on the posterior surface near the lesser curvature. Dr. Decker of Würzburg has the last word on the subject (*Berl. Klin. Wochenschrift*, No. 21), and he advances evidence in support of the initial lesion being traumatic, or rather thermal. Thus, he believes that the contact of hot thickened fluids with the gastric mucosa excites hyperæmia, which becomes localised, and may lead to venous stasis and hæmorrhage in a limited territory, with all the subsequent necrotic changes. He supports his view, not only by reference to the clinical history of cases of gastric ulcer (he points to the great prevalence of gastric ulcer among cooks, who habitually test the flavour of their dishes when very hot), but by two experiments on dogs into whose stomach food heated to 50° C. was introduced. In one of the animals a patch of hyperæmia, with hæmorrhage between the gastric mucosa and muscularis near the lower curvature, was found; in the other, a deep ulcer of characteristic shape and position had been produced.

BOARDING OUT OF PAUPER CHILDREN.

SOME recent statements as to the condition of children boarded out at Denmead by the St. Pancras Board of Guardians seem, at first sight, calculated to discredit that mode of bringing up pauper children. At one place, it was stated, four children were found sleeping in one room with a thatched roof. A woman named Sylvester had six children of her own, two from Mr. Barnardo's Homes, and one from the St. Pancras guardians. These boys were described as sleeping three in a bed, and "covered with festering sores." Four were in a deplorable state, and had no doctor attending them. An old man with six shillings a week had four boys boarding with him—two from Mr. Barnardo's Homes and two from St. Pancras. When visited, the boys were standing at their dinner round a table one eating out of a broken gallipot and another out of a broken basin. The only food which they were seen to have by the visitor consisted of pieces of pork rind and of bread and potatoes. The whole family used one towel, which did not seem to have been washed for two months. These statements have, however, been very largely disputed or refuted. Mr. Barnardo has had the boys from his school brought up to be inspected, and he declares that they are quite well and free from sores, save one boy who has constitutional eczema, and even he is much better than when he went away. The agent from Mr. Barnardo, making a surprise visit on the very night the statements were published, found the beds and clothing clean. All the children appeared to have had ample food. The vicar of Denmead, Mr. Greene, describes the reports as grossly exaggerated, and attributes the eruptions noticed to children affected with itch sent down from St. Pancras. But Mr. Clarke, the medical officer, denies that any child with the slightest indication of disease has left St. Pancras, and his carefulness is vouched for by Mr. Millward, clerk to the St. Pancras Board, in an interview with the representative of the *Pall Mall Gazette*. It seems right to conclude that a system which has been found on the whole to work well should not be condemned on such doubtful statements as have gone the round of the press. But it is evident that the system requires close supervision, either by the guardians themselves or by some one person or number of persons in whose vigilance and wisdom they can place confidence. Mr. Millward spoke favourably of the system, and said the St. Pancras guardians had nine districts in various parts of England to which they sent children to be boarded out.

THE MICROBES OF PNEUMONIA.

PROFESSOR WEICHSELBAUM of Vienna, in the course of a review of the discoveries made concerning the etiology of acute pneumonia (*Centralblatt f. Bacteriolog.*, Nos. 19 and 20), refers to his own researches, which are of much interest. Dealing with material from 129 cases, which comprised not only primary croupous pneumonia, but also lobular and secondary forms, he distinguished four kinds of bacteria. The most common was a diplococcus, mostly of an oval shape, sometimes occurring in small chains, and having a capsule which stained faintly. Its cultures had some resemblance to those of streptococci; and when injected into the pleural cavity of rabbits caused a fatal result in from one to two days, with bilateral lobar or lobular pneumonia, pleuritic exudation, and often also peritonitis and pericarditis. This microbe is identical with Fränkel's pneumococcus, but differs from Friedländer's, which does not affect rabbits, but does affect guinea-pigs. It was found ninety-four times in the 129 cases, seventy-eight times in genuine croupous pneumonia, but also in secondary and lobular pneumonia. A second variety, far less frequently present, was the streptococcus pneumoniæ, distinct from other forms of streptococci, and occurring in secondary (lobar or lobular) pneumonia when the primary disease was excited by a streptococcus. It was also met with in other forms of secondary pneumonia, and even in primary lobar pneumonia, associated or not with the diplococcus. Less frequently still (viz., in nine cases only) did he meet with an organism identical with Friedländer's pneumococcus, which Weichselbaum styles "bacillus pneumoniæ." He found this not merely in lobar croupous pneumonia, but even in lobular pneumonia, and three times in association with the diplococcus pneumoniæ and a streptococcus. Lastly, the staphylococcus pyogenes aureus was found in five cases, either alone or in company with the diplococcus, and always in secondary inflammation. In several observations these various microbes were also detected in the exudation of inflammatory processes complicating the pneumonia—as

Digitized by Google

pleurisy, pericarditis, peritonitis, meningitis, &c., and once in the blood and splenic pulp. Weichselbaum concludes from these facts that genuine croupous pneumonia is in most cases caused by the diplococcus pneumoniæ; but undoubtedly in a few the bacillus pneumoniæ seems to be the sole agent. Clinically, he observes in a footnote, these latter cases seem to run an exceptionally malignant course. Acute lobular pneumonia, and the pneumonias (lobar or lobular) which are secondary to other infective diseases, may be due to either of the four above-named organisms, either alone or combined. Therefore the pneumonic virus is not a single entity, but, just as in acute inflammations of connective tissue, several kinds of bacteria may be the cause of the morbid process.

LONDON WATER SUPPLY.

THE report of General A. de C. Scott, the water examiner for the metropolis, gives an account of the chemical composition of the different waters, which still contain a large amount of chlorine, and discusses the methods of collecting water adopted by the different companies, mentioning that the Grand Junction and other companies have constructed in the beds of gravel and sand which overlie the London clay, in the bottom of the river valley, open-jointed distributing and collecting conduits, the former being used to convey the river water to the gravel or ballast beds, and the latter placed at a lower level to collect the water after it has passed through the ballast, and convey it to the well of a pumping engine, by which it is lifted into the reservoirs for ordinary filtration and distribution. At Hanbury, near Sunbury, a brick-lined tunnel, 1550 feet in length, has been driven through the clay underlying the gravel, and from the tunnel vertical pipes lead to the base of the gravel, from which pure water flows into the tunnels. The gravel beds in this locality form, General Scott says, a valuable source of supply, the importance of which should be recognised. It must, however, he adds, be borne in mind that this, like all shallow sources of water in porous subsoils, is liable to become fouled by extension of population over the surface; and if houses with a system of cesspools were built on the gravel area adjoining the works of the water companies, the purity of the supply therefrom might become seriously endangered.

ACTION OF HYOSCINE ON THE EYE.

DR. O. WALTER of Dorpat has published a series of observations on the action of hyoscine on the eye. This body produces some toxic effects very similar to those produced by atropine—viz., dryness of the throat and dilatation of the pupils—but, unlike atropine, it causes drowsiness and languor; it also sometimes causes nausea and giddiness. Until lately little has been known of the effects of hyoscine on the eye, but within the last few months two other Dorpat students, working under Professor Kobert's direction, have paid some attention to the subject—one of them, Dr. Sohrt, having published a paper on the general, therapeutic, and physiological effects of hyoscine. Hirschberg and Emmett had, however, remarked the mydriatic action of this subject. Dr. Walter experimented on animals by instilling hyoscine into one eye and atropine into the other, and found that a drop of an exceedingly attenuated solution produced distinct dilatation, acting both on the pupil and on the accommodation much more rapidly than atropine. The dilatation passed off more quickly than that produced by atropine, but the paralysis of accommodation persisted about as long as that produced by an equally strong solution of atropine. No decided effect was remarked on the intra-ocular pressure, but in patients with chronic glaucoma the regular application of hyoscine certainly produced an improvement in the sight and an enlargement of the field of vision. Slight toxic symptoms were produced by two drops of a 1 per cent. solution. The author recommends repeated applications of a weak solution in preference to a single application of a strong one.

THE HEALTH OF THE GERMAN CROWN PRINCE.

THE news that Dr. Morell Mackenzie had been hastily summoned to Potsdam to see the Crown Prince has attracted the attention of English readers to his Imperial Highness's illness, and naturally excited some alarm, which we hope may be groundless. It appears that for some time the Crown Prince has suffered from hoarseness and laryngeal irritation, which a stay at Ems did nothing to mend. A laryngoscopic examination revealed the presence of a growth from one of the vocal cords, and it was feared that it was malignant in nature. Under these circumstances Dr. Morell Mackenzie was summoned to the illustrious patient, and he, to solve all doubts, removed a portion of the growth with laryngeal forceps, and submitted it to Professor Virchow for microscopical examination. We are glad to see it stated that his report was to the effect that the growth is not malignant. This has allayed the grave fears that had been entertained in some quarters.

ALLEGATIONS AGAINST THE HOVE SANATORIUM.

IT is a great pity that persons who evidently do not properly understand the general principles on which infectious hospitals ought to be established should publicly condemn a hospital which, in their own district, has been erected in order to protect the population against infection. But this is what has been done at Hove. We, of course, do not refer to complaints as to such matters as dampness of plaster, ill-fitting doors, &c. These are at times noticeable in new buildings, and where sea-sand is used on walls the former condition is by no means uncommon. Such faults should obviously be remedied; but the work can be done quietly without wholesale condemnation of the hospital. The more important matters complained of are such as, if wrong, cannot easily be remedied, and to these we would draw attention. The alleged defaults, it was stated, had led to the institution being the very reverse of what it should be. First, complaint was made of the distance of one block from another, which rendered the passage of attendants difficult. We cannot assume that an ordinary attendant, properly clothed, could not be expected to pass from one block to another; otherwise how can tradesmen, doctors, and other people who have to go to the hospital face such weather as is supposed to exist in what is admittedly a breezy spot? Apparently it was considered that nurses and attendants should be running to and fro between the ward blocks and the administrative building. But that is precisely what ought to be hindered. A nurse, when told off to her ward duty, should remain in her ward until her time for duty is over, and then, putting on such out-door clothing as may be necessary during cold weather, she should return to the administrative cottage, which is her home. She will thus suffer no more than if she dressed for a walk in the same breezy place. So, also, the food supplies should three times a day be brought in a properly covered apparatus to each ward block by a suitably clothed person. What is wanted is, above all things, to prevent communication between ward blocks containing different infectious fevers, and to keep the several buildings aerially quite distinct. Another objection raised is that the nurses must take their food in the infected wards. They certainly have no need, and the place must be badly administered if they are allowed to do so. A proper administrative building has been provided where the nurses are expected to live when off duty, to eat, and to sleep. Then, again, it is said there are no rooms or conveniences for an attendant in the isola-

Digitized by Google

tion block. A special room for a nurse is no more needed than in the case of a nurse who is looking after a private case in a house, and, what with the separate rooms and conveniences for nurses in the administrative block, we do not see what more could be wanted. Enough has been said to show how unfortunate this publicity has been. Some details of repair apparently want seeing to; but before such hospital provision is condemned in public again, it would be better that those who criticise it should visit other modern infectious hospitals built on approved systems, and learn what their experience has been.

TRANSPLANTATION OF HUMAN BONE IN A CASE OF UNUNITED FRACTURE.

On March 28th M. A. Poncet of Lyons read a paper before the Académie des Sciences on a case in which he had transplanted a piece of bone for ununited fracture of the tibia. The patient, aged nineteen, had sustained a compound fracture of the tibia about the middle of the shaft thirteen months previously; this had been followed by necrosis. On Jan. 19th half of the first phalanx of the big toe, measuring about one inch in length and half an inch in width (the articular ends having been removed), from the recently amputated limb of a healthy man aged forty-three, was inserted between the fragments after having been soaked in sublimate solution for three minutes. Antiseptic precautions were taken and the graft did well, but at the end of two months the tibia was still movable, and M. Poncet decided to resect the fibula and tibia. It was then found that there had been very little loss of substance on the part of the graft, which was united firmly to the lower fragment of the tibia by fibrous tissue, but was separated by about a quarter of an inch from the upper fragment by weak fibrous material.

PROFESSOR BILLROTH.

WE regret to learn that the distinguished Vienna surgeon is dangerously ill, and that his condition excites the anxious fears of his friends and medical attendants. He is suffering from a severe attack of bronchitis; this in itself would not occasion serious alarm in a man of his age—fifty-eight—and robust nature. Unfortunately, it is complicated with weakness of the heart, which adds to the gravity of his condition. Our Vienna correspondent, however, as will be seen by his letter, printed in another column, mentions the publication of a bulletin which favours the indulgence of a hope of the recovery of the great surgeon—a hope which will be shared by surgeons all over the world.

A MEDICAL PRACTITIONER A CO-RESPONDENT.

ON Saturday last, in the case of Pittis *v.* Pittis and Wiley, in the Divorce Court, we regret to note that a member of our profession was the co-respondent. The respondent, Mrs. Pittis, was the wife of Mr. Richard Roach Pittis, a solicitor and the town clerk of Newport, Isle of Wight. They were married in 1881 and lived happily until a year or two ago. In 1883 Mr. Thomas Ormsby Wiley came to Newport as an assistant to another medical man, and afterwards succeeded him. Mr. Wiley became the medical attendant of Mr. and Mrs. Pittis, who had no children till 1886. It was not till the year 1885 that the petitioner had reason to think that Mr. Wiley's visits to his wife were too frequent and of something more than a professional character, and not indeed till a much later period that he doubted the behaviour of his wife. Then, however, evidence was unmistakable, and when the cause came into court the case against Mr. Wiley was so complete that he did not appear, and no defence was attempted. It was proved that he had taken advantage of his professional position and encouraged an interchange of visits with the respondent for which there was no excuse. These visits were at such times and in such circumstances as to be inconsistent with the innocence of either party. The judge spoke in the highest terms of the conduct and bearing of the petitioner, and in a very different way of the conduct of the medical man. The jury agreed to a verdict without leaving the box, and awarded damages to the amount of £1200, and the judge ruled that the petitioner should have the custody of the child. It is humiliating to think that a medical man should be found in such a position. While it is our part to defend medical men who in the discharge of their duties are exposed to the slander of the malicious and the extortionate, it is not less our duty to denounce in the strongest terms those who do not demean themselves in a manner consistent with the character required in the members of a profession where purity and highmindedness are so essential to the public welfare.

MEMORIAL PORTRAIT OF SIR WILLIAM JENNER, BART., K.C.B., M.D., &c.

NUMEROUS friends and many former pupils of Sir William Jenner have, for some time past, desired that there should be an enduring memorial of one so generally and so highly esteemed, and who has attained to so distinguished a position in his profession. With this object a preliminary meeting has been held, and Sir William Jenner has consented to sit for his portrait to Frank Holl, Esq., R.A., to be presented to Sir William by the subscribers; a replica to be presented to the Royal College of Physicians, and to University College, London.

In order that as many as possible of Sir William Jenner's friends and former pupils may take part in the memorial, it has been decided that any sum, however small, may be subscribed, and that the names only, and not in any case the sum subscribed by each, be published. A committee is in course of formation, and anyone desiring that his name be added thereto should signify the same without delay to one of the following:—Dr. C. J. Hare, 15, Manchester-square, W.; G. D. Pollock, Esq., 36, Grosvenor-street, W., hon. treasurers; Dr. J. Russell Reynolds, 38, Grosvenor-street, W.; Sir Henry Pitman, M.D., 28, Gordon-square, W.C., hon. secretaries, to any one of whom subscriptions may be paid.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Professor Carl Friedländer, a brief account of whose labours will be found in another column.—Professor J. E. Areschoug, the well-known Swedish botanist, in his seventy-seventh year.—Dr. A. de Waal Malefijt, a distinguished Haarlem surgeon.—Professor Castorani, the Naples ophthalmologist.

THE EDUCATION OF CHEMISTS.

THERE can be no doubt as to the benefits which have accrued from the Pharmacy Acts of 1852 and 1868. And there can be no reasonable objection to an extension of these Acts in the direction of giving power to enlarge the education of chemists, so long as the distinction between it and that of medical men is kept clearly in view. It is vain to charge the Medical Council and eighteen or twenty subordinate bodies with the duty of upholding the standard of medical education if Parliament with its other hand sanctions a *quasi*-medical education in chemists. We trust, therefore, that care will be taken in the Pharmacy Act now before Parliament to give no such sanction, and to eliminate from the curriculum of chemists such subjects as are the proper study of medical men. We have good reason to

Digitized by Google

elieve that the best teachers of pharmacy appreciate ıe limitation of their duties, and, while giving the clearest ıstruction as to the nature and character of drugs, most ıefully avoid disquisitions on their medical uses and ıerapeutical properties.

THE "TEAR" OF PUBLIC LIFE.

SURELY the sort of life lived by members of the House of ommons just now is *tear*, not wear. The worry of it all bad enough, but the wretched squandering of energy in ll-night sittings, which has come to be the rule rather than he exception of late, is little, if at all, short of suicidal. nless there be an entire change of tactics shortly, there will e a hideous roll of mental and physical wrecks to chronicle. he "tear" is already telling very seriously on many valuable ves, and before long the mischief in progress will make itself anifest. We think it in no way beyond our province, as n organ of the profession whose business it is to advise the ublic on matters of health, to warn those whom it may rgently concern that there is a real and instant peril that, nless something be speedily done to spare Ministers and embers of the House of Commons the fearful and prolonged train to which they are now, and have been for some time ast, subjected, there will be a catastrophe which men of all arties and ways of thinking and acting in politics cannot ail to regret.

INNERVATION OF THE PYLORUS.

THE state of the pylorus has been observed under various rtificial conditions by M. Dobbert, who has employed bags f caoutchouc filled with air and introduced within the yloric ring of rabbits; the variations in the movements of he pylorus were written on a kymograph, with which the aoutchouc bag was put in communication by means of ubes and tambours. M. Dobbert finds that the pylorus is in a state of continual tonus, and at the same time may exhibit nder certain conditions movements of further contraction nd dilatation, apparently induced in a reflex manner. ocal anæmia and electrical excitation of the vagus and of he spinal cord at the point of origin of the tenth dorsal pair ause increased tonicity of the pylorus, whilst local asphyxia nd electrisation of the upper part of the spinal cord have the pposite relaxing effect. The tonus is sometimes increased, ometimes diminished, by excitation of the splanchnic.

ST. MARY'S HOSPITAL.

ON the 19th inst. Sir E. H. Sieveking was elected Consulting Physician to St. Mary's Hospital, and Dr. J. Braxton Hicks Obstetric Physician. Dr. Lees, the senior out-patient physician, fills the vacancy caused in the staff of in-door physicians. Mr. Edmund Owen was formally re-elected Surgeon to the institution, and Dr. Walter Pearce was appointed Assistant Physician.

PNEUMONIA IN THE HELDER GARRISON.

DR. H. A. JANSEN, a Dutch military surgeon, reports an interesting series of cases of croupous pneumonia occurring during his term of duty at the military hospital of Helder. Though in five years he only saw three cases in private practice, the number admitted into hospital with this affection was forty-seven. The cases came exclusively from two rooms in the barracks, the occupants of the other parts of the building and of the married men's quarters, which were close by, entirely escaping. The climatic influences and the exposure on sentry duty were of course shared by the whole garrison alike; so that it is very difficult to account for the apparently exceptional susceptibility of the occupants of the two rooms, the hygienic and other conditions being at least as satisfactory as in other parts of the barracks. It should be remarked that a large proportion of the cases were far from typical, some of them presenting several of the appearances of enteric fever. As a rule, however, the symptoms were not very severe. Two out of the forty-seven died. In the rare instances in which the pyrexia was very marked antipyrin was given, with satisfactory results. Other cases were treated with an acid mixture, together with brandy, musk, and camphor where there was much prostration.

PROFESSOR HYRTL.

THE illustrious Vienna anatomist, Hyrtl, who has for some time been suffering from cataract, has had the right eye operated on by Prof. Fuchs, apparently with great success. The left eye is also affected, and will shortly have to be operated on. Prof. Hyrtl is seventy-five years of age. He has the sympathy and good wishes of medical men in every country, who have all, probably, whether they are aware of it or not, profited more or less by the excellent use to which he put his organs of vision in his earlier days.

SEA WATER FOR STREET WATERING.

ON the 12th inst. at Bournemouth an important inquiry took place at the instance of the Local Government Board with respect to an application from the Bournemouth Commissioners for sanction to borrow £9000 for works of street watering and sewer flushing. The scheme was opposed by the local Gas and Water Company, no objection being raised by the ratepayers. Evidence in favour of the proposal was given by the Bournemouth surveyor, the borough engineer of Portsmouth, the borough surveyor of Great Yarmouth, the consulting analyst for the county, and Mr. Kinsey-Morgan, medical officer of health for Bournemouth; and a shareholder in, a director of, and the secretary to the Water Company, opposed it. The Local Government Board will shortly come to a decision on the matter; we have frequently supported the suggested use of sea water for such purposes, and cordially hope that the London Board's decision may be in favour of the promoters of the scheme.

THE WIDOWS AND ORPHANS OF MEDICAL MEN.

THE admirable Society for the Relief of Widows and Orphans of Medical Men, whose generous rules leave every medical practitioner in the metropolitan district without excuse for not providing something for his own widow and orphans if need be, and for not lending a helping hand to less fortunate practitioners if there be no such need, will soon have completed a century of useful existence. Next year will be the centenary of its foundation. We are glad to hear that its officers propose to celebrate the event in a manner worthy of the great and good objects of the Society. We shall welcome the occasion, and trust that it will excite much attention on the part of medical men to the subject of provision for widows and orphans.

CHEMISTS AS MEDICAL ADVISERS.

MR. WILLIAM CARTER lately held an inquest on the body of a woman who had died without medical attendance, and with only the advice of a chemist. He said it was a great pity that persons should consult chemists instead of medical men. He said the evil was increasing and it was time something should be done to lessen it. It caused a great number of unnecessary inquests and much expense to the country. This is a serious view of the matter; but it is the least serious one. There can be but little doubt that many such deaths might be obviated by proper medical care and attendance, which can be had in every parish

Digitized by Google

for nothing if the patient is too poor too pay. The coroner's remarks are opportune at this moment when a Pharmacy Bill needs to be amended in such a way as to preserve a broad distinction between the education of medical men and that of chemists.

GASEOUS RECTAL MEDICATION IN PHTHISIS.

A FRESH series of observations by M. Perret appears to result in conclusions in general harmony with other recent trials of the method. He states that the gaseous injections have no microbicidal action; they can modify the bronchial phenomena and diminish expectoration, also influence nutrition for good, especially in the apyretic forms, like other medicaments, and hence are of value in relieving particular symptoms. The outcome of this appears to be that they are as good as, but no better than, other bronchial remedies.

FOREIGN UNIVERSITY INTELLIGENCE.

Basle.—Dr. M. Gottschau, Professor of Topographical Anatomy, has resigned.

Berlin.—Dr. B. Fraenkel has been raised to the status of Extraordinary Professor lecturing upon laryngology. Dr. Jürgens, first anatomical assistant in the Charité, has been appointed Curator of the Pathological Institute. His post as first assistant will be filled by Dr. O. Israel. Dr. Matthias Schulz, director of the Royal Vaccination Institute, has been appointed to assist Professor R. Koch in giving instruction to all the students in vaccination.

Buda-Pesth.—Dr. O. Pertig has qualified as *privat docent*.

Prague (Bohemian University).—The names of Dr. Schwing and Dr. Bubesca have been selected for the vacancy caused by the death of Professor Streng.

Tübingen.—Dr. Walcher, *privat docent*, has been appointed to the post of Superintendent and chief instructor in the Stuttgart Midwives' School, in place of Dr. Fehling recently appointed Professor of Midwifery at Basle.

THE members of the Society for the Prevention of Hydrophobia and Reform of the Dog Laws are preparing for submission to the Government a comprehensive Bill intended to abrogate all existing laws affecting dogs, and place their hygienic control and general management upon clear and well-defined lines. The co-operation and advice of all interested in this question are invited by the secretary of the Society, but the fact that the Duke of Beaufort is its president, and that several professors of the Royal Veterinary College are on its committee, is sufficient proof that the true interests of dogs are being cared for, as well as the public protection.

WE regret to hear that throughout the county of Lincolnshire petitions are being signed protesting against the proposed pension of £600 to Dr. Palmer, who has for many years acted as medical officer to the County Lunatic Asylum; Gainsborough having taken the initiative, the other boards are following suit. The reason given for the protest is the present depressed condition of agriculture, but it is to be hoped that Dr. Palmer will not be deprived of the reward of his long and faithful services to the county.

WE understand that the restriction which has been hitherto imposed upon the President of the Medical Board at the India Office with respect to practice in the case of sick officers or *employés* of the Indian Government on the active list has now been withdrawn by the Secretary of State for India in Council, this decision having been officially communicated to Sir Joseph Fayrer in a letter bearing date May 23rd.

THE charges of criminally assaulting two female patients, brought against Mr. Ralph Hodgson, a medical practitioner of Lewisham, were investigated at the Central Criminal Court on the 24th and 25th inst. In the first case the jury returned a verdict of not guilty, a decision which was received with applause; and in the second, no evidence being offered, a formal verdict of acquittal was recorded. We congratulate Mr. Hodgson on having succeeded in vindicating his character from a charge which of all accusations is the most difficult to disprove, and most fatal to those against whom it is made.

THE death of Mr. H. F. Gisborne is announced as having occurred, in his seventy-ninth year, at his residence in Derby on the 25th inst. The deceased was a justice of the peace for the county and borough, and consulting surgeon to the Derbyshire General Infirmary. For upwards of fifty years Mr. Gisborne was intimately associated with public affairs in Derby, and was the ninth member of his family who, during the last 200 years, had filled the civic chair.

THE Cavendish Lecture will be delivered at the West London Hospital on Friday, June 3rd, at 8.30 P.M., by Sir Andrew Clark, the subject being, "On a frequently successful and speedy Method of treating Hay Fever."

THE dignity of Knight Commander of St. Michael and St. George has been conferred on James Hector, M.D., Director of Geological Surveys and Curator of the Colonial Museum for the Colony of New Zealand.

MR. F. BOWREMAN JESSETT, F.R.C.S. Eng., has been elected one of the vice-presidents of the Surgical Section of the International Medical Congress to be held at Washington in September next.

MR. EDGAR M. CROOKSHANK, M.B., has been appointed Lecturer on Bacteriology at King's College, London.

THE LONDON HOSPITAL.

LAST Monday the first lecture of a course on Chemical Pathology, arranged to meet the requirements of fourth year's students, or those who have recently qualified, was given at the London Hospital by Dr. Ralfe. The lecture, which was introductory to the course, dealt with the Relations of Humoral Pathology to Therapeutics. The history of humoral pathology was traced back to the teachings of Galen, and the domination of the idea of black and yellow bile, and their respective influence on the fluids of the body. The general distrust of the Galenic doctrines, or, rather, disgust at their dogmatism, was then alluded to as setting in at the end of the fifteenth century, as preparing the way for the acceptance of the teaching of the iatro-chemical school in the sixteenth century. The rise of the two great schools—the anatomical and the chemical—was then described; how at first there was a hearty union between them, and great anatomists like Sylvius, Willis, and Vieussens, who were also great chemists; how the schools became rivals, and at last deadly enemies. It was interesting to observe, said the lecturer, that the more speculative school—the chemical—was from the first associated with Germany, whilst the more practical—the anatomical—found its chief adherents among the Latin races. He defended the iatro-chemical school against the charges brought against it. The real cause of its failure was its being unable to verify its facts, neither chemistry nor physics being sufficiently advanced to render assistance. Having drawn attention to the importance of applying chemical analysis to animal physiology, the iatro-chemists could do no more than wait till chemistry was sufficiently

Digitized by Google

advanced to afford further assistance. Although pathological chemistry was eclipsed for more than a century and a half, it did not die. It was fortunately preserved by the Dutch School of Medicine, which during the whole of the eighteenth century exercised a potent influence over medical thought. It was this school that first made pathological anatomy a science, and took the anatomist from the dissecting-room to the deadhouse. Dr. Cullen, who was a pupil of Boerhaave's at Leyden, was next to see that scientific chemistry, advanced as it was by that time, might play the same part to pathology that anatomy was then doing, and from that time chemistry, no longer attempting to dominate medicine with its speculative views, consented to work as a servant, and chemical pathology has, in consequence, become a recognised science based on experimental facts. "*Chymia egregia ancilla medicinæ, non alia pejor domina.*" One great result of Cullen's teaching was the creation of a school of medicine at Edinburgh, which soon distanced its Dutch rival, and became at the commencement of the century the leading school of medicine in Europe. Dr. Ralfe then proceeded to enumerate the chief results obtained by this union of scientific chemistry with practical medicine during the present century, and remarked that everything was tending to a new alliance with the anatomical school, to unite in work for the common good. After paying a tribute to the work done by Prout, Golding Bird, Bence Jones, and others, the lecturer eulogised Dr. Garrod as the Nestor among the humoral pathologists of the day. Chemical pathology owed him much, not only for the brilliant discoveries he had made and their practical utility, but for the cautious manner and sobriety with which he had advanced his generalisations, and which had conferred such credit on the young and rising school.

ST. GEORGE'S HOSPITAL.

A VERY successful gathering took place at this Hospital on the occasion of the opening of the new physiological laboratories and class room. On May 18th, in addition to the present students, there was a very large attendance of old St. George's men and other friends of the hospital. An interesting address was delivered by Mr. G. D. Pollock, in which he reviewed the various changes and improvements he had witnessed, both in the medical profession generally and in the hospital in particular, during the past fifty years. Congratulating the medical school on its good fortune in having secured the services of Dr. Delépine as lecturer and general superintendent of the physiological department, Mr. Pollock referred at length to some remarks which Dr. Delépine had made to him with regard to this department, over which he now presides: "For a number of years physiological facts have been taught in the form of dogma, the student remaining in ignorance of the simplest methods of demonstrating facts. Hence the facts and the theories arising from them were received on the mere authority of the discoverer, this being taken as equivalent to actual demonstration, and the result was but too often erroneous teaching." Great stress was laid by Dr. Delépine upon the fact that this new laboratory is so fitted and arranged that any student with proper industry can work out for himself all questions which fall within the curriculum, and that it is independent work of this kind which is so profitable. Mr. Pollock then proceeded to give a sketch of the hospital as it was when he entered the Medical School, and dwelt, amongst other advantages which the present student enjoys, upon the fact that house-surgeons, dressers, &c., held their appointments free of charge, an inestimable boon in the case of the house-surgeon or house-physician, who holds his appointment at St. George's for twelve months. Mr. Pollock then introduced the question of increasing the number of house-physicians and house-surgeons in order to meet the daily augmenting work of the hospital. Such a plan for adding to the resident staff would, Mr. Pollock said, receive his hearty support, as conducing alike to the welfare of the patients and the better education of those who are to form the rank and file of the medical profession. Mr. Pollock concluded an instructive address with a few words of advice to the students, and a graceful compliment to the dean of the school, Dr. Wadham. Those present, at the request of the dean, then proceeded to inspect the new laboratory, where Dr. Delépine made a few physiological experiments with a view of showing the capabilities of the building for the purpose for which it was intended. A subsequent adjournment to the museum for refreshments concluded the meeting, which had been agreeable and satisfactory to all concerned.

MEDICAL ATTENDANCE ORGANISATION COMMITTEE.

AT a meeting of the above committee, held on Tuesday, May 24th, the following resolutions were carried unanimously:—

1. "That it is desirable that hospitals should enter into arrangements for co-operation with provident dispensaries in their neighbourhoods, and that a subcommittee be appointed to prepare a scheme defining the relations that should subsist between them." The following were appointed as a sub-committee to consider this resolution: Sir Spencer Wells, Drs. W. Ord, Gilbart Smith, W. E. Steavenson, J. Grey Glover, Walter Smith, F. H. Alderson, and J. C. Steele; Mr. W. G. Dickenson, Mr. W. Bousfield, Lieut.-Col. Montefiore, and Mr. W. G. Bunn (secretary).

2. "That the governing bodies of hospitals be requested to consider the advisability of attaching a provident branch to the out-patient departments." This resolution having been passed, it was also resolved that the chairman (Sir Spencer Wells) should select a subcommittee to consider the best means to carry it out.

The next meeting of the committee will be held on Tuesday, June 14th.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Jarrow Urban District.—Under the Jarrow Improvement Act 140 notifications of infectious disease were heard of during the past year, and much useful work was done by excluding scholars from houses infected. One section of the Act contains a useful prohibition. It enacts that no person shall cease to occupy any house within six weeks of the occurrence of a case of infectious disease therein without having the house disinfected to the satisfaction of a medical practitioner, or intimating the nature of the disease to the owner; and breach of this provision led to the infliction of a fine during the year. Typhus was twice imported, but it did not spread, and Dr. Munro attributes the low "fever" death-rate of the town, even in such a period of privation as has been gone through, to the considerable sanitary improvements which have been brought about. Amongst the more prominent additions to the sanitary defences of Jarrow is the completion of an excellent hospital for infectious diseases. During a previous year it was found that the bye-laws as to drainage for new buildings had not been observed, and the method of dealing with such cases gave rise to much discussion. As a matter of fact, in any town where much building is going on it is nearly the work of a single officer to see that building bye-laws are duly observed, for constant supervision during the process of building is imperatively necessary.

Bristol Urban District.—Dr. D. S. Davies, who during the last six months of 1886 held the post of medical officer of health in succession to his father, gives an excellent summary in his annual report of the various sanitary circumstances existing in Bristol. On many points details are given which must be of great local value. As regards the water-supply, it is stated to be, in point of quality, above suspicion; but it is to be regretted, in connexion with a special charge which the company have the power to make as to each closet flushing apparatus, that the majority of the out-door closets throughout the city are dependent on hand flushing. As regards the sewers, Bristol is a city without sewer ventilation, and Dr. Davies supports our contention that roadway ventilators are injurious. Much is being done in the direction of efficient house drainage, but additional

Digitized by Google

powers are needed, under bye-laws, as to securing proper foundations for houses. In one respect we regret to see so little advance in Bristol. Scarlet fever caused no less than eighty-nine deaths last year—a fatality which indicates a vast amount of sickness. There is a fever hospital, and yet the admissions numbered nine only. It is difficult to understand the grounds on which this hospital is administered as it is, for one of the regulations for admission not only reminds patients that a charge not exceeding £1 a week will be demanded of each such patient, but it goes on to add that this payment "will be enforced" in all cases where such patient or person is able to pay. Anything more calculated to prevent the use of a hospital built and maintained at the cost of the rates, professedly for the public protection, it is almost impossible to conceive, and it is, we assume, largely owing to this statement as to the enforced payment of a comparatively paltry sum of money that so little is done by way of isolation to stay the spread of a disease so fatal and so costly to the community suffering from it. Happily, authorities generally understand that the public interests demand isolation at almost any reasonable cost, and the question of procuring repayment is rarely entertained to any noteworthy extent.

Spilsby Rural District.—In connexion with an account of the infectious diseases which have come under notice during the past year, Dr. F. J. Walker refers to the advantages of notification, isolation, and disinfection. As regards isolation, he believes that the plan hitherto adopted, of taking cottages as hospitals as occasion may require, will still answer the purposes of the district; and it would appear that disinfection is limited to such work as can be carried out in the absence of an efficient disinfecting apparatus. The general description of the several localities in the district affords indication of action needed in the direction of providing proper water, sewers, privies, &c., and of the want of action as regards houses that are a nuisance from dampness or otherwise. The death-rate for 1886 was 17·45 per 1000.

Bedford Rural District.—Dr. Prior calculates the death-rate of this district at 16·27 per 1000 for 1886, and he then proceeds to give some account of the infectious diseases that have prevailed during the year. Small-pox has been held at bay during ten years, and it is earnestly hoped that, even with the risk of fresh importation, this disease may soon become extinct in the district. Diphtheria was to some extent prevalent in Kempston, and owing to the absence of a hospital belonging to the sanitary authority one case was isolated in the Poor-law small-pox building in the workhouse grounds. Dr. Prior presses upon the authorities in the Bedford Union the necessity for some central hospital on the block system, and adapted to serve the requirements of their districts.

Wem Rural District.—Dr. Giles reports that scarlet fever was widely prevalent in the district during the last six months of 1886, and he refers to the need for notification of such diseases. He points to the strange anomaly that if a farmer can trace the loss of one of his pigs to the fact that a neighbour has failed to give notice of the existence of infectious disease on his premises the latter is subject to a heavy fine, but if the farmer only loses one of his children from a similar cause there is no penalty. In Wem itself good results have followed from the new arrangements as to the removal of town refuse. In Shawbury the need for a proper supply of water is pressing. Throughout the district the death-rate was 18·9 per 1000.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5701 births and 3594 deaths were registered during the week ending May 21st. The annual rate of mortality in these towns, which had been 20·9 and 19·7 per 1000 in the preceding two weeks, rose again last week to 20·3. During the first seven weeks of the current quarter the death-rate in these towns averaged 20·6 per 1000, and was 1·9 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 12·3 in Wolverhampton, 14·2 in Leicester, 14·9 in Sunderland, and 15·2 in Halifax. The rates in the other towns ranged upwards to 28·1 in Preston, 28·8 in Oldham, 29·2 in Norwich, and 31·1 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 548 and 500 in the preceding two weeks, rose again last week to 532; they included 237 from measles, 158 from whooping-cough, 48 from scarlet fever, 47 from diarrhœa, 22 from diphtheria, 19 from "fever" (principally enteric), and only 1 from small-pox. No death from any of these zymotic diseases was registered during the week in Wolverhampton; whereas they caused the highest death-rates in Newcastle-upon-Tyne, Norwich, Salford, and Oldham. The greatest mortality from measles occurred in Newcastle-upon-Tyne, Manchester, Oldham, Salford, and Norwich; whooping-cough in Birmingham, Oldham, and Blackburn; and scarlet fever in Preston, Salford, Halifax, and Blackburn. The 22 deaths from diphtheria in the twenty-eight towns included 12 in London, 2 in Liverpool, 2 in Salford, and 2 in Oldham. Small-pox caused 1 death in London, but not one in any of the twenty-seven large provincial towns. Only 5 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; no new case was admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 348 and 294 in the preceding two weeks, further declined last week to 289, and were 25 below the corrected average. The causes of 79, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bradford, Cardiff, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Hull, Halifax, Sheffield, and Huddersfield.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 31·3, 36·6, and 24·4 per 1000 in the preceding three weeks, rose again to 25·4 in the week ending May 21st. During the first seven weeks of the current quarter the death-rate in the city averaged 30·4 per 1000, the mean rate during the same period being but 18·5 in London and 19·5 in Edinburgh. The 172 deaths in Dublin last week showed an increase of 7 upon the number in the previous week; they included 8 which were referred to measles, 6 to whooping-cough, 5 to scarlet fever, 4 to "fever" (typhus, enteric, or simple), 1 to diarrhœa, and not one either to small-pox or diphtheria. Thus 24 deaths resulted from these principal zymotic diseases, against 19 and 20 in the preceding two weeks; they were equal to an annual rate of 3·5 per 1000, the rates from the same diseases being 2·5 in London and 2·4 in Edinburgh. The fatal cases of measles, which had been 11, 6, and 9 in the preceding three weeks, were 8 last week. The deaths from scarlet fever, whooping-cough, and "fever," on the other hand, showed an increase upon recent weekly numbers. The deaths of infants corresponded with the number in the previous week, while those of elderly persons showed a further decline. Three inquest cases and 5 deaths from violence were registered; and 51, or nearly a third, of the deaths occurred in public institutions. The causes of 17, or nearly 10 per cent., of the deaths registered during the week were not certified.

ZYMOTIC DISEASE IN AUSTRIAN TOWNS.

We recently called attention to the high rates of mortality that prevailed during last year in the Austrian towns, having a population exceeding 10,000 persons. The forty-nine towns embraced by this return had an estimated aggregate population of rather more than two millions and a half in the middle of 1886; and the mean death-rate in the year was equal to 31·7 per 1000, against 20·9, which was the mean rate in the twenty-eight large English towns, with an estimated population of more than nine millions. Thus the average population of the forty-nine Austrian towns was little more than 50,000, while the English towns had a mean population more than six times as great. A comparison of the mortality from the principal zymotic diseases in the Austrian and English towns throws considerable light upon this marked difference of mortality. The deaths from the principal diseases of this class caused a mean death-rate of 5·11 per 1000 in the Austrian towns, whereas in the English towns it was but 2·88. Small-pox caused 1015 deaths in the Austrian towns, equal to 0·38 per 1000, while only 70 deaths from this disease occurred in the twenty-eight English towns, giving a rate of but 0·01. The rates from measles and scarlet fever in the Austrian towns differed but slightly from the rates in the

Digitized by Google

English towns; while that from "fever" was 0·33, against 0·23 in the English towns. The death-rate from whooping-cough, however, which was 0·53 in the English towns, did not exceed 0·21 in the Austrian towns. Diphtheria and croup caused 2233 deaths in the Austrian towns, equal to a rate of 0·83, which was more than five times the rate in the English towns. It should be borne in mind that in the disease classification now used in England croup is not classed with diphtheria, but, after due allowance for this cause of difference, diphtheria mortality is undoubtedly very much greater in Austria than in England. In Trieste and in sixteen other smaller towns the death-rate from diphtheria in 1886 exceeded 1 per 1000; and in a smaller town, Drohobucz, with a population of 18,896, the death-rate from this disease exceeded 3 per 1000. The mortality from diarrhœal diseases also accounted for a considerable proportion of the excess of mortality in the Austrian towns. The mortality from these diseases, which did not exceed 1·16 per 1000 in the English towns, was equal to 2·62 in the Austrian towns: it should be noted that 0·22 was referred to cholera; but if this be excluded, the diarrhœal rate in Austria was more than double the rate in the English towns. The Austrian return also shows a remarkable excess of mortality from inflammatory diseases of the respiratory organs and from phthisis, the rates from these diseases being equal to 3·75 and 6·38 per 1000 respectively. The Registrar-General's Annual Summary does not give similar information for any of the large English towns except for London, where the rate from diseases of the respiratory organs last year was 4·41 and that from phthisis 2·01 per 1000 respectively. Thus inflammatory diseases of the lungs and phthisis caused a death-rate in the Austrian towns greater by 3·71 per 1000 than the rate in London. The return also affords conclusive evidence of a marked excess of infant mortality. It may therefore be safely assumed that the startling excess of mortality last year in the Austrian cities was mainly due to high rates of zymotic and infant mortality, and to excessive fatality of diseases of the respiratory organs and of phthisis, thus affording conclusive evidence that the excess may be attributed to defective sanitary condition, such as prevailed in most of our largest English towns less than half a century ago.

"Audi alteram partem."

THE COLLEGE OF SURGEONS' EXAMINATIONS.

To the Editors of THE LANCET.

SIRS,—The very large proportion of failures at the examination in Surgery at the Royal College of Surgeons is too important a matter to be allowed to drop from the notice of the profession, and it is to be hoped that the prominence you have given to it will be the means of eliciting the opinions of those best able to judge. I do not propose to ask whether the fault lies at the door of the students, of their teachers, or of their examiners, although it is doubtful if the teaching of surgery were ever carried out with greater care and thoroughness than now, while the students of to-day are certainly not less industrious than their predecessors. Having often availed myself of the privilege of Fellows of the College to be present at the surgical examination, I will ask to be allowed to mention one or two features of the examination which, I believe, account in some measure for the distressing proportion of failures.

I think all examinees will admit that *vivâ voce* examination is more trying and embarrassing to a candidate than is a written paper, and the fact that the paper only carries one-third of the total of marks at the College of Surgeons makes this examination an unusually severe test. I am aware that very strong arguments are urged in support of the present system, and I do not suggest that it should be altered; but I submit that every care should be taken to diminish the evil of the system, and to eliminate from the *vivâ voce* examination the elements of chance which all must admit are very prone to characterise it. Special pains ought to be taken to put a candidate at his ease by commencing the examination with some simple questions. It is obvious that a "time limit" introduces a special difficulty, and it seems to be a pity that there are no means by which the examiners can prolong the examination of slow students or shorten that of obviously quick and proficient ones.

Another difficulty that candidates have to contend with is the low scale of marking. It must often be impossible to decide whether a given candidate should have two or three or four out of a possible five, and for the simple reason that twenty-five or thirty-five out of fifty really represent the value of his answers. This is a matter that might be easily altered, and I cannot help thinking that it would tend to make the examination more satisfactory. But, Sirs, these are, after all, minor points, and I would submit that the main requisite is, as you mention in your article, greater attention to the art of examining. It should be more generally recognised than it is that it is not an easy matter to examine well and so to frame questions as to at once show the examinee their purport. So far as my experience goes, the main complaint of candidates at the College of Surgeons is that they mistake or quite fail to understand the meaning of examiners' questions, and I am confident that there is much that is just in this complaint. If examiners would prepare for the examination with a tithe of the care they demand of the students, I should confidently anticipate a marked diminution in the percentage of "plucks," and a fair approximation of the result of the examination to the actual state of the students' knowledge.

I should like to add, in reference to Mr. Heath's letter, that his statement that the standard of the examination has been lowered of late is quite contrary to the general impression in metropolitan medical schools, and is quite opposed to the confident opinion of at least one of his colleagues in the Court. Mr. Heath's explanation of the large percentage of failures in the recent examinations is hardly satisfactory, for, of course, the number of reappearances is dependent upon the number of men "plucked" at previous examinations.

I am, Sirs, your obedient servant,

May 24th, 1887. A. PEARCE GOULD.

To the Editors of THE LANCET.

SIRS,—Your leader of May 14th has, I am sure, been read with pleasure by many who are interested in the welfare of the College of Surgeons, and especially by those who have had a practical experience of its late final examinations. Having undergone this experience on four occasions (the fourth only being a "lucky" one), a few remarks from a candidate's point of view may be of service, if taken together with the letter from the pen of Mr. Christopher Heath, contained in THE LANCET of last week. Credited with two years profitably spent under the old apprentice system at a county infirmary—twenty-one months of provincial and fifteen months of metropolitan hospital attendance on the one hand, against three rejections at the Royal College of Surgeons' final examination on the other, —I have, needless to say, long since come to the conclusion with Mr. Heath, that at this examination "one man may be lucky, &c."; but many will not agree with him when he goes on to say that he fails to see, "human nature being as it is, how it is to be avoided." Again, Mr. Heath writes that "a good deal has been done to improve the College of Surgeons' examination, with the object of gaining less uncertainty, and even in the way of diminished stringency." Yet in the preceding paragraph he tells us that (notwithstanding these improvements) the rate of "pluck" was in January 50 per cent., and in April 51·6 per cent.—a percentage which he attributes to an unusually large number of "reappearances" in January and April. But why should a man who has the misfortune to be referred, and has spent that term of reference in honest work at his hospital, be more likely to fail than one who has never experienced the examination, especially when a second appearance is so common? The obvious conclusion to be drawn from these statements seems to be that, whatever improvements have been made, they have not remedied the evil. Your leader above referred to, I believe, rightly attributes the uncertain results of these examinations to the "comparatively high value set upon the oral examinations," and especially to the fact that the "personal equation plays a prominent part" in the result. To this may be added the different standards which exist at the various tables, and the fact that in the clinical examination one candidate may be given six or seven or even nine cases to diagnose, whilst

Digitized by Google

another is kept during the same time at two. He who makes a correct diagnosis in four out of seven cases has an advantage over his more unfortunate fellow-candidate who succeeds only in one of two cases. When there is more uniformity, not only in the number of clinical cases allotted to each candidate, but also as regards the nature of the questions in the oral examination, and above all in the method of marking in that department, then, and not till then, may we expect uniform results. By all means let a high standard of proficiency be maintained, but if this can only be done by the sacrifice of justice, the sooner means are taken to remove what is becoming a cause of reproach to the College the better, not only for the College, but for all who have the honour to hold its diploma.

I am, Sirs, your obedient servant,

May, 1887. M.R.C.S.

ON THE ADMINISTRATION OF CARBONATE OF LIME AS A MEANS OF ARRESTING THE GROWTH OF CANCEROUS TUMOURS.

To the Editors of THE LANCET.

SIRS,—Dr. Hood's interesting paper in THE LANCET of May 7th encourages me to communicate some details of a case under my own observation which, I think, are to a great extent corroborative of his testimony as to the probable value of lime in cancer.

Rather more than four years ago, my late partner, Dr. Wilson Iles, performed an amputation of the left breast for scirrhus of unusually rapid growth. The patient, an unmarried lady aged forty-two, was stout and of florid complexion. I was not present at the operation, but I chanced to look in just as the tumour was being examined, and although I had no reason at that time for taking special notice of the matter, I distinctly remember the characteristic "apinoid" section as the mass was laid open. A preparation of this was made, but it has unfortunately been mislaid or lost. I discovered, however, amongst Dr. Iles' microscopic slides one which exhibits some large diptychal cells, which, if I am not mistaken, came from the same specimen. Not the least doubt, as far as I know, was entertained as to the nature of the tumour, but I had no personal connexion with the case until two years later, when I was consulted by the patient, after long delay and hesitation on her part, about the other breast. This presented a tense, incompressible, lobulated enlargement at the lower and outer part, deeply attached, the skin partially adherent and the nipple retracted, with dilatation of the superficial veins and induration of the axillary glands. There was no ulceration and no pronounced constitutional cachexia, but the expression was careworn and anxious. She complained of acute lancinating pain, radiating from the nipple, and it was only to obtain such temporary relief from this as would allow her to sleep at night that she appealed to me, since she declared most positively that nothing would induce her even to listen to the suggestion of another operation. Neither she nor I doubted for a moment that the cancer had recurred, though from the increased rapidity of its growth, as well as from certain sensations elicited by palpation, I was led to suspect that it was rather of an encephaloid than a scirrhous character. I prescribed a little chloral and sundry anodyne applications, which were varied from time to time, being of little or no effect. For several months I had no conversation with the patient, but I judged from her physiognomy that the disease was making its usual hideous progress. Shortly after this, at a meeting of the West Herts Medical Association, I heard from Dr. Hood of the calcined oyster-shells. Greatly impressed with the desirability of affording so simple and innocuous an agent a trial, I sought out the lady, and, disregarding her prohibition ever to mention the subject, I told her that there was a remedy which might cure her if she would steadily persevere with it for at least a year, which might fail, but which could not possibly in either event do her any material harm. Obtaining her promise to take this regularly without further question, I supplied her with a quantity of dried carbonate of lime, adding thereto 2½ per cent. of the phosphate, to imitate the product of the shells as nearly as possible. I have since been told by Professor Attfield that the true proportion should have been about 1 per cent. Of this she was to take as much as would lie heaped up on a sixpence three times daily, in a dessertspoonful of milk; stirred up in a larger quantity of fluid, a great part of the powder settles before it can reach the lips, and is apt to be overlooked at the bottom of the cup, while a dessert-spoon is introduced bodily into the mouth and the milk hides the disagreeable appearance of the lime. Last week I examined the breast for the second time. The lime has been administered now for nineteen months, with very rare omission of the daily doses. During that time I have purposely avoided any allusion to the matter, and have congratulated myself on the patient's own reticence. But I have remarked that her countenance has been more placid and content during the past year, and that she has long since ceased to write to me for soothing lotions or liniments. The growth of the tumour is undoubtedly arrested. I do not like to say positively that its bulk is diminished, because I took no actual measurements, and two years is a long time to retain a mental impression which may be relied upon for comparison, but I am decidedly of opinion that it is smaller. Whether this and the result generally proceed from simple mechanical diminution of vascularity, or more remotely by alteration of nutrient innervation, I do not pretend to know; but there is certainly a healthier aspect of all the surrounding tissues. The implication of the skin and retraction of nipple still persist, of course, but no tenderness remains, or the slightest appearance of any proneness to ulceration. I should add that there is no apparent evidence of calcification.

It is somewhat curious that burnt and powdered oyster-shells are held in great estimation as a remedy for various ailments and injuries in many parts of the world. Certain tribes of South American Indians make pills of this substance, which they swallow as a preventive of hunger on long journeys, and it was thought at one time, like chopped-up hair, to augment the sustaining virtues of pemmican.

I am, Sirs, yours truly,

Watford, May 14th, 1887. ARTHUR STRADLING, M.R.C.S.

THE TREATMENT OF RINGWORM.

To the Editors of THE LANCET.

SIRS,—During the early part of my medical career, I served the time-honoured apprenticeship of five years. The family consisted of the usual number of adults and two little children. These children were unfortunate enough to catch ringworm of the scalp (nobody knew how), and notwithstanding the application of every known or suggested remedy, they managed to keep the disease for nearly three years. It was with peculiar pleasure, derived from old reminiscences and experience, that I read your recent leading article on the subject, which so accurately detailed all the troubles incident upon that nasty disease. Now the nature of the disease is well known, and you will think I make a bold assertion when I say that the disease is to be cured with one application, and without the unsightly shaven head.

In the first place, the remedy must be in the hands of the medical attendant alone; secondly, procure a rough brush of the prescribed pattern, best represented by a penny gum brush with the bristles cut very short; then take a sufficient quantity of pure glacial carbolic, warm and liquefy it in a watch glass, and then rub it into the roots of the hair until all is thoroughly touched and no further application is necessary; but the head may be washed from time to time, when necessary, with a lotion of sulphurous acid. The principle is to destroy the spores of the fungi which cause the disease. Have clothes disinfected.

I am, Sirs, yours truly,

Leamington, May, 1887. F. E. WILKINSON, M.D.

RANK OF MEDICAL OFFICERS IN THE ARMY.

To the Editors of THE LANCET.

SIRS,—Although the subject of the rank of medical officers in the army has been lately well ventilated in your columns, perhaps you will kindly let me trespass very briefly on your space to endorse most thoroughly the views so clearly and tersely put forward last week by "Brigade Surgeon." I have recently had opportunities of discussing the question of honorary rank with many senior officers of the department, and I am glad, for our credit's sake, to find that one and all scout the notion of purely military titles being thrust

Digitized by Google

on us. Speaking, then, for many of my brother officers, I say, we do *not* want to be captains and colonels; we do *not* want to sink our profession by adopting titles utterly incongruous; we do *not* want (putting it plainly) to become the laughing stock of the army. I should like to assure students and others who contemplate entering the medical service of the army that they need not for one moment be dissuaded from doing so by this question of rank. If a medical officer is a gentleman in the true sense of the word, as well as a careful, painstaking professional man, he is sure of the respect and esteem of his military brethren; his status and rank as an army surgeon are accorded him, and he need never wish to sail under false colours. This is my experience after twenty-five years happily spent in Her Majesty's service. I am, Sirs, yours obediently,

May 24th, 1887. ARMY SURGEON.

THE UTILITY OF DRUGS IN THE TREATMENT OF DISEASE.

To the Editors of THE LANCET.

SIRS,—As a general practitioner, I cannot allow Sir Wm. Gull's remarks, made at the meeting of the General Medical Council on May 12th, to pass unnoticed. For a man of his position, thought so highly of by the public as he is, to make the statements that "people did not get well by drugs," and that "it was the duty of the medical man not to give drugs," was, to say the least, injudicious, not to use a stronger term. It would be absolutely wasting the space of your valuable paper to argue against such utter nonsense, as the value of drugs in certain diseases is beyond all question. Sir Wm. Gull said that the Prince of Wales, when suffering from typhoid fever, did not have four doses of medicine; but we know that, of all severe diseases, typhoid fever is the one above all others that requires little or no medicinal treatment. Sir Wm. Gull also considers a warm bed when you are sick better than all the general practitioners. It would be interesting to know whether he considers a warm bed when you are sick better than all the consulting physicians, because, if he does, it is quite evident he has found a panacea for all ills—viz., a bed and a warming pan. I am, Sirs, yours truly,

Streatham, S.W., May 24th, 1887. GEO. STEELE PERKINS.

ENTERORAPHY.

To the Editors of THE LANCET.

SIRS,—I should not have ventured to trespass on your space, after your full account of the meeting at the Medical and Chirurgical Society, had not the time at my disposal for replying to the discussion been so limited that I was forced to omit, or pass very rapidly over, points which deserved much more notice. I shall be glad if you will allow me the opportunity of making these clearer. And, first, the objection raised as to the respective length of time taken by the performance of Lembert's and my own suture. Is it reasonable to compare the time taken to use Lembert's stitch by a surgeon accustomed to use it with the time taken by the same surgeon in using mine, to which he is not accustomed? Moreover, the risk to the patient in these operations is not so much in the length of time which the entire operation absorbs, although that is important, as in the length of time during which the bowel is outside the abdomen, and exposed. This dangerous time I claim to be far shorter during the use of my stitch than with any other, for whilst my own can best be done with only the cut ends exposed at the level of the skin wound, the whole of the rest being reduced, no other stitch can safely be used in this position; in which case the bowel wall lying outside is further irritated by the constant friction produced by the removal and replacement of warm towels, sponges, &c., to say nothing of the ever-varying temperature to which it is thereby subjected. With regard to the total penetration of the bowel by the stitch, as opposed to the partial one of Lembert, I should like to point out that sutures are useful for two reasons, the latter of which appears to be overlooked: first, as a means of approximating tissues designed to unite; and, secondly, as a means of exciting plastic inflammation in those tissues, and thereby securing their union. Union of the intestine has two distinct stages, in each of which distinct tissues are involved; in the choice of a method of suture regard should be had to both. The first epoch is occupied by the union of the peritoneal surfaces; this is apparently immediate, or almost so, but temporary. During this period the plastic lymph effused covers in any sutures which may be used; but the point here is that, in so far as stitches and knots irritate a peritoneal surface, so far and so much adhesion from effused lymph is to be expected. Now, whilst this is wanted between the opposed surfaces of divided ends, it is not wanted between these and the peritoneal surfaces of viscera and abdominal wall around, where adhesion would be harmful. It will readily be appreciated that whilst the knots in Lembert's stitch are outside the bowel, and so tend to excite such production of plastic lymph on the neighbouring surfaces, forming subsequent adhesions, which will be more or less permanent in proportion to the length of time during which these sutures remain *in situ*, in my stitch the knots and threads are separated from the new-formed peritoneal sac by the whole thickness of the bowel, and therefore can have no such action. Inasmuch as all sutures pass at last into the lumen of the bowel, and not into the peritoneal cavity, it is unnecessary to speculate whether or not they could do any harm there. But the secondary or permanent union takes place by connective tissue formed partly from the cellulo-fibrous layer of Gross, and partly from the subserous layer. Gross himself, in describing his experiments on animals and their results, pointed out that the main permanent union was due to the action of the cellulo-fibrous layer, and the microscopical sections shown by me demonstrate perfectly this fact, as well as the share taken by the subserous layer. Now, bearing in mind the second reason for the use of sutures, is there not an advantage in the passage of the suture through both these layers in the production of a firm and satisfactory result? The comparison between the ligature around an ovarian stump and these sutures is manifestly no parallel at all. The conditions are absolutely different. In the one a stump is left which is no longer to have any further office to perform in the economy; and the more thoroughly this is bound down by adhesion, so long as no band is formed under which a loop of bowel may be caught, the better. In the other, an attempt is made to restore the *status quo ante* in an organ, one great essential in the efficiency of which is its complete freedom of movement: in proportion as this is obtained will the operation be really successful. It will be seen at once that this comparison will not hold water. Moreover, in any case in which symptoms of sudden obstruction appeared, would not the fact of a previous ovariotomy, other things being equal, lead the surgeon to suspect internal strangulation under a band resulting therefrom?

This letter is already too long, or I should have liked to answer also the objection to operations on dogs; but doubtless such answer is perfectly apparent.

I am, Sirs, yours truly,

G. STANMORE BISHOP, F.R.C.S. Eng.

Manchester, May, 1887.

FORK SWALLOWING.

To the Editors of THE LANCET.

SIRS,—Cipriani, to whom you referred in a recent number, while imitating the exploits of a juggler in swallowing a fork, some sixteen years ago, allowed it to pass into his œsophagus beyond his control. After various attempts at extraction, made by himself, his friends, and his wife, he was, on the following day, transferred to the Ospedale de Santa Maria Nuova, where also all efforts at removal were unavailing. Several ingenious instruments were invented for the purpose, but failed. He remained in the hospital for five weeks, suffering more or less inconvenience, moral as well as physical, for the public were divided in opinion, some proclaiming him only a fool, others an impostor. A year or so afterwards, having produced severe pain, hæmorrhage, and other untoward symptoms, it was ascertained that the fork had effected its exit from the stomach, and passed into the intestines, accompanied with a relief to the more urgent phenomena; motion, however, occasioned severe suffering. He now wandered from place to place, a subject of interest to some, of ridicule to others, till three or four weeks ago he was attacked by acute pleurisy of the right side, terminating in effusion, and was admitted into the Ospedale di San Giovanni di Dio. Recovering from this, attention was again directed to "the

Digitized by Google

fork," which was discovered in the right iliac fossa, pointing obliquely upwards to the left side. It was evidently fixed in this situation, for palpation effected no change in its position, and considerable enlargement could be detected in the immediate neighbourhood. After long hesitation, he consented to an operation, which was performed by the distinguished surgeon, Professor Rosati, aided by his skilful assistant, Dr. Catani. An incision was made extending from an inch and a half below the umbilicus perpendicularly down to the pubes, and after considerable difficulty the fork was extracted from the ascending colon, the blunt end pointing upwards. There had been long and constant inflammation, as was proved by the great thickening of the bowel, adjacent tissues, and the firm adhesion of the colon to the abdominal parietes. The bowel was opened, the edges secured to the abdominal integuments, and the wound dressed in the usual way. The fork measured twenty-two centimetres, and presented but little erosion; for though the plating had disappeared, the extremities retained their original defined outlines. The time could not be calculated which it had taken in reaching its ultimate destination, but probably many years, judging from the condition of the surrounding textures. The patient bore the operation well, and was very anxious to secure possession of the fork as conclusive evidence against his detractors. There has been no fever or unfavourable symptom, and the wound is nearly healed, there remaining only a small fistulous opening communicating with the intestine. I will not take up your space by any remarks on this strange history of the journey of a fork.

I am, Sirs, yours truly,

Florence, May 9th, 1887. WILLIAM WILSON, F.R.C.P. Lond.

A SUGGESTED IMPROVEMENT IN ETHER INHALERS.

To the Editors of THE LANCET.

SIRS,—The object of this letter is to call attention to the fact, as it appears to me, that the arrangement of anæsthetic inhalers has not kept pace with discoveries in medicine, at all events of the bacteriological branch, and to suggest one remedy which seems to me successful so far as Clover's ether inhaler (than which I know none better) is concerned. Almost as soon as I commenced to administer ether, it struck me that for patient after patient to respire air from a bag which in the meantime had not been cleansed was certainly an indelicate proceeding. If patients were aware that they were doing so, many of them would object to submit to it. But it was not until I was one evening listening to a discussion on tubercle at the West London Medico-Chirurgical Society that it occurred to me that this repeated use of the same bag was also possibly injurious, for most believe now in the tubercle bacillus, and practically there is, it seems to me, every facility for its getting into the air-bag of an ether inhaler, such as Clover's, supposing the patient using it to be suffering from phthisis, possibly undiscovered. Again, patients may be anæsthetised while developing infectious zymotic disease, and I am not sure that in this way such diseases may not have been propagated. If these premisses are conceded, what is the remedy? I am informed by an eminent physiologist that the ether would not render the bacillus or germ inert. Well, then, the apparatus should be cleansed. This is not difficult, except as regards the air-bag, and the improvement I would suggest is an india-rubber bag the same size as that now in use, but of as thin a material as possible (it could scarcely be made too thin), so that it may be of so little cost that there would be no hesitation in throwing it away after use, a new one being used for each patient. Messrs. Maw, Son, and Thompson, of Aldersgate-street, have been very kind in preparing samples of the proposed bag for me. It would be possible to keep, say, half-a-dozen of the ordinary bags going—turning them inside out after use, cleansing and drying them before use again; but this would be less certain and more troublesome than renewing the very much cheaper bag which I have described. I am, Sir, yours obediently,

RICKARD W. LLOYD, M.R.C.S.,
Anæsthetist to the West London Hospital.

Russell-road, Kensington, W., May, 1887.

VACCINATION GRANT.—Mr. T. H. Tidswell, of Morecambe, Lancaster, has received the Government grant for successful vaccination (fourth time).

LIVERPOOL.

(From our own Correspondent.)

THE ASSIZES.

THE criminal business of the Spring Assizes for South-west Lancashire has just concluded, having been of nearly three weeks' duration. The medical officers of H.M. Prison at Walton will have a considerable addition to their already large experience of corporal punishment, Mr. Justice Day having ordered the punishment of the "cat" in many cases, combined with a comparatively short term of imprisonment. There were no convictions for murder, but two very aggravated cases of manslaughter: one in which a man set his wife on fire; another in which the prisoner kicked his wife to death. Among the other cases was that of a man charged with throwing a stone at a policeman, which struck him in the left eye. He was taken to the Royal Southern Hospital, where he was attended to by Dr. Dixon, and subsequently on his discharge from the hospital by Mr. F. W. Lowndes, surgeon to the police, and Mr. E. A. Browne, of the Eye and Ear Infirmary. The worst effects of the injury were observed posteriorly, the choroid and retina being torn across. Very little sight remains, the officer being only able to distinguish night from day. The prisoner was acquitted.

HOSPITAL SATURDAY.

The total amount advised to the treasurer up to May 21st was £2132. More returns have still to be made, and it is expected that this sum will be considerably increased.

THE WEATHER.

The unseasonable weather which has prevailed elsewhere has been especially marked here. It may be doubted whether any predecessor of this merry month was ever celebrated with so much influenza, winter clothing, and fires. It has influenced the mortality returns, as might have been expected, elderly people suffering severely from the effects of so unseasonable a spring after a long and trying winter.

Liverpool, May 25th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE EXHIBITION.

ALTHOUGH the weather has been anything but favourable for our Exhibition, the attendance for the past week was over 76,000. There is one circumstance acting adversely—namely, the great strike in the coal trade, which has gone on now for nearly seventeen weeks, causing a cessation of employment to over 20,000 persons; but at last there appears a prospect of this great dispute being arranged. Very little, I fear, is thought of its effect on the medical profession, but it is a heavy loss to all having colliery appointments, as of course there is no pay, and the doctor has more to do, with the exception of accidents, than when the miners are working. Among the models at the Exhibition of interest, I might mention the model dwelling erected under the superintendence of the Model Dwelling Sanitary Committee, to illustrate principles of design, construction, sanitation, decoration, and furnishing—an example of a healthy, convenient, comfortable, and complete detached residence. The model of the floating hospital on pontoons lately described in this correspondence and constructed for the Tyne Port Sanitary Commission, is also full of interest as regards hospital sanitation, and is itself the best hospital model I have ever seen.

THE PRUDHOE CONVALESCENT HOME.

The annual meeting of this Convalescent Society has just been held at its noble home at Whitley. Drs. Philipson and Baumgartner read the reports, which showed that the number admitted during the year had been 1469; of that number, 446 were from Northumberland, 486 from Newcastle, 529 from Durham, and the remainder from Yorkshire and Cumberland. Of the whole number, 1272 were cured, 149 were greatly relieved, 15 were somewhat better, 29 were *in statu quo*, and 4 died. It is pleasant to add that, although the expenses of this beneficent institution had been very

Digitized by Google

heavy, the financial year had closed with a substantial balance in the hands of the treasurer. Dr. Philipson may well be proud of the position of an institution to which he has devoted years of labour.

DEATH CERTIFICATES: A CAUTION.

At the Newcastle police court last week, Mr. W. Hardy, a gentleman in practice here, was summoned by the superintendent registrar of Newcastle and district for making out a certificate contrary to the Registration of Births and Deaths Act of 1874. It was shown that Mr. Hardy had not seen the deceased during his life, but he was attended for him by his assistant. It was pleaded that, although there had been some irregularity, it was the practice of some practitioners, when their assistants attended, to sign the certificates, and that the deceased did actually die from the complaint stated in the certificate. The bench, however, held that it was a very irregular practice, and inflicted a fine of £2 and costs. But it should be remembered that often great pressure is put on practitioners by the poor to give them certificates, which are often granted out of pure good nature without fee or reward. Medical men here will, however, do well in future to protect themselves from being placed in a false position and undergoing a very troublesome prosecution.

MEASLES IN THE NORTH.

There is a pretty extensive epidemic of measles at Seaham Harbour. Many adults have been attacked also at Morpeth, where the infant mortality is said to be so severe as to have become a subject of pulpit reference.

Newcastle-on-Tyne, May 24th.

EDINBURGH.

(From our own Correspondent.)

PRESENTATION TO DR. JOSEPH BELL.

LAST week Dr. Joseph Bell was presented with his portrait at a large meeting of his friends and admirers. The presentation was made in the hall of the Royal College of Surgeons, which was well filled, and the meeting was of an enthusiastic character. In opening the proceedings, Dr. Littlejohn referred to the family name borne by Dr. Bell as a household word in the history of surgery in Edinburgh, and spoke of the services rendered to the school and to the public by him during his thirty years' connexion with the Royal Infirmary. This connexion was inaugurated in 1856, when Dr. Bell entered the institution as a dresser, and ended last year, when he retired with the rank of senior surgeon on the acting staff. Mr. Fleming spoke of the warm enthusiasm and respect with which the students regarded their old teacher, and of their appreciation of his great powers as a clinical lecturer. The portrait was then unveiled amidst great applause, and was formally presented by Dr. Argyll-Robertson, President of the College of Surgeons, who presided. Dr. Joseph Bell then expressed his thanks in a few happily framed sentences. The picture is an excellent likeness painted by Mr. J. Irvine, and bears the inscription: "Presented to Joseph Bell, M.D., F.R.C.S.E., on the termination of his appointment as surgeon to the Edinburgh Royal Infirmary, by numerous students of the School of Medicine, and by many professional friends in town and country. 1887."

POST-GRADUATE COURSES.

A meeting of the committee that arranged the series of post-graduate courses held in September and October of last year was summoned for Monday last, when the programme for the course for the coming autumn was discussed and provisionally settled. The demonstrations which were so highly appreciated last year are to be repeated, and their scope in some instances considerably extended. A number of additional courses not included in last year's programme will probably be added to this year's list. The arrangements for the course will be finally completed and published at the end of the present month. The time selected is the same as that adopted last year—viz., the last week in September and the first two weeks in October, a period previously found most fitting the convenience of the lecturers and of those attending their demonstrations.

Edinburgh, May 24th.

DUBLIN.

(From our own Correspondent.)

THE QUEEN'S BIRTHDAY HONOURS.

IN celebrating Her Majesty's Jubilee, it is sincerely to be hoped that the profession in Ireland will not be overlooked in the dispensing of birthday honours, and that both the medical and surgical branches may receive that recognition from Her Majesty's advisers which they are undoubtedly entitled to. Successive Governments have treated the leaders of the medical profession in this country in a niggardly and ungenerous manner, and no excuse can any longer be made for the systematic ignoring of their claims to State honours. Scattering distinctions broadcast in England, and to a less extent in Scotland, while Ireland has been markedly neglected, can scarcely be regarded with equanimity by the members of the profession in this country. Confining my remarks at present to the surgical branch, there is one—a leading member of it—possessed of the highest surgical talent, gifted with great eloquence, and in every respect well fitted to receive a mark of Her Majesty's favour. Need I mention the name of Sir William Stokes, the President of the Royal College of Surgeons in Ireland, whose term of office has been filled in an exceptionally brilliant manner, and who has well deserved the highest honour which the Fellows of his College have conferred upon him. His claims for recognition cannot be disputed, and I am confident they will be favourably considered by Her Majesty's advisers.

ROYAL UNIVERSITY OF IRELAND.

The medical degrees obtained by the successful candidates at the spring examinations of this University were conferred last week by the pro-Vice-Chancellor, Sir Robert Kane.

ROYAL COLLEGE OF SURGEONS.

A meeting of the Fellows will be held on Saturday, June 4th, to receive the report of the Council for the past year; and on the following Monday the annual election of office-bearers for the ensuing year will take place. In addition to the names of candidates already mentioned for a seat on the Council may be added that of Mr. William Frazer, for many years a member of the Court of Examiners of the College.

THE QUEEN'S JUBILEE: BANQUET BY THE INCORPORATED LAW SOCIETY.

Sir William Stokes, President of the Royal College of Surgeons, responded to the toast of "The Medical Profession" at the banquet given by this Society on Monday last in honour of Her Majesty's Jubilee. He said that it was deserving of recognition, not alone on account of the fact that its great aims and objects were the alleviation of suffering, but also because it furnished an arena for the cultivation of all the sciences which might directly or indirectly tend to promote human good; and there was another reason—because it counted among its ranks so many who are devoted to works of mercy and of charity, and who are and had been true citizens and loyal men. It was a subject of congratulation to him that his tenure of office as President of the Royal College of Surgeons had been contemporary with two great events—the Jubilee year, and the union recently formed between the two great medical corporations, the King and Queen's College of Physicians and the Royal College of Surgeons. This union he looked upon as an official recognition of the fact that the barrier which had been erected years ago by foolish men, separating medicine and surgery—a barrier productive of much mischief, which tended to promote division, and which kept the two professions powerless and weak—had been shattered by the unerring artillery of common sense. Now that this union had been effected, they might look to the realisation of that which was their great aim and object—this mutual overlapping of their work, which would lead to unity in medical science.

MEDICAL MAGISTRATES.

Brigade Surgeon T. Barnwell, retired A.M.D., has been placed on the Commission of the Peace for co. Dublin.—T. J. Stafford, M.D., of Tangier, Boyle, has been appointed to the Commission of the Peace for co. Roscommon.

Dublin, May 24th.

BELFAST.

(*From our own Correspondent.*)

QUEEN VICTORIA CONVALESCENT HOME FOR CHILDREN.

A SHORT time ago the committee of the Children's Convalescent Home in connexion with the Belfast Hospital for Sick Children made a request, through Mr. Wm. Ewart, M.P., to Her Majesty the Queen, soliciting her patronage and permission to use her name in connexion with the Home. An answer has now been received to the effect that Her Majesty has been graciously pleased to command that the said institution shall be known as "The Queen Victoria Convalescent Home for Children." The amount required to build and endow the home is £3300, and already the sum of £1240 8*s*. 5*d*. is announced as received or promised. A pleasing feature in this movement is that the working men are co-operating with the committee, and have arranged to have collections in the various manufactories in and around Belfast.

ACCIDENT TO MR. STEWART OF GLASSLOUGH.

About three weeks since, Mr. Stewart of Glasslough sustained a fracture of the leg in the neighbourhood of the ankle joint, and, after an attempt at saving the limb had been made, it was found necessary to amputate. Mr. Hall and Mr. Young of Monaghan, Mr. Palmer of Armagh, and Mr. Huston of Tynan have been attending him, and I understand he is doing well. About the time the accident occurred arrangements were being made to present him with a testimonial, a sufficient indication of his popularity in the dispensary district of Glasslough, and this has now been done.

BELFAST ROYAL HOSPITAL.

From the report presented at the quarterly meeting held on May 23rd, we learn that during the past three months there were 499 in-patients, 233 medical and 216 surgical; while during the same period 3260 out-patients received treatment. The expenditure of the hospital up to the end of April has been £5938 0*s*. 3*d*., and this added to the debt at the close of last year of £1048 8*s*. 2*d*. makes a total expenditure of £7086 8*s*. 5*d*. The receipts from all sources have been £9804 4*s*. 4*d*., but of this sum the bequests (£3500) have been invested, so there remains an excess of expenditure over income at the end of April of £682 4*s*. 1*d*. The board state that the hospital is in all its departments in a most efficient condition. As explained before, one of our merchant princes, Mr. Foster Green, has offered to build a wing for the treatment of consumptive cases on condition that a sum of £15,000 is raised to endow the hospital, so that this department would not be a drag on the institution. Between £7000 and £8000 have been raised, and it is hoped that before the end of the year, the time up to which Mr. Green's offer extends, the remainder will be subscribed.

Belfast, May 24th.

VIENNA.

(*From our own Correspondent.*)

THE ILLNESS OF PROFESSOR BILLROTH.

THE state of Professor Billroth, who is suffering from bronchitis capillaris and pneumonia catarrhalis, was very serious on Friday last. There was considerable debility of the heart's action, and a catastrophe was feared. But after inhalations of pure oxygen the patient had rallied by the next day. The bulletin just published is confirming the hope of a speedy recovery of the illustrious surgeon. He felt himself greatly relieved, the appetite was good, and he slept soundly for some hours.

THE VIENNA HOSPITAL QUESTION.

A great deal of public excitement was recently caused by a speech of an Austrian deputy, Herr Pernerstorfer, on the bad condition of the Vienna General Hospital. An endless series of grievances relating to the bad boarding and nursing of the patients was animadverted upon. The Government was induced to order an inquiry on the state of the affairs, and the physicians of the General Hospital have been examined by a commission consisting of officials of the Government (*Statthalterei*). So far as I can gather, the statements made by Herr Pernerstorfer on the mismanagement prevailing in the General Hospital seem to be proved by the evidence obtained from the physicians of the hospital. The examinations are continued daily. By a decree of the governor of Lower Austria the introduction of a book of grievances in all public hospitals has been ordered. But it is hoped that this impracticable measure will soon be withdrawn. The director of the hospital, Herr Hofrath Hofmann, has not as yet asked to be relieved of his duties, as had been reported by the daily newspapers, but having suffered some time ago an apoplectic attack, he obtained sick leave for Baden, near Vienna.

NEW TREATMENT OF GRANULO-FUNGOUS INFLAMMATIONS.

In the clinical wards of Professor Albert I had recently occasion to see some cases exhibiting very favourable results of a new method for treating granulo-fungous inflammations, which seems to deserve the attention of medical practitioners. By theoretical considerations and by experiments made on animals, Dr. Gustav Kolischer, one of the pupils of Professor Albert, has been induced to try the local application of phosphate of lime in cases of fungous disease. The results obtained by this treatment were in all cases highly satisfactory. The medicament, which is prepared by adding phosphoric acid to the water in which the phosphate of lime is dissolved, was administered by injections into the diseased parts, or by dressings impregnated with the salt. The majority of the patients treated with phosphate of lime were children between six and twelve years of age. There were two cases of white swelling of the elbow, with ankylosis, fever, and pain; after six weeks they were cured, with perfect freedom of movement. In another case of fungous disease of the knee with pain, the mobility was partly restored after four weeks' treatment. With similar results some cases of caries manus in children and adults were treated. The most remarkable case was that of extensive destruction of the knee joint by granulo-fungous inflammation in a boy twelve years of age, with hectic fever, severe pains, necrosis, and large cavities in the bones. The cavities having been stuffed with phosphate of lime gauze, recovery proceeded quickly; after three weeks the cavity was filled with fair granulations up to the surface, and the fever and pain ceased. The use of phosphate of lime proved also very efficacious in a case of tuberculous fistula of the rectum, which resulted in perfect recovery. But this remedy has some disadvantages. It exerts a slightly irritating effect, and causes pain, which continues during the first six hours after its application, and is followed by fever, which lasts a day or two.

A NEW AUSTRIAN PHARMACOPŒIA.

As nearly twenty years have elapsed since the Austrian Pharmacopœia was revised, the Minister of the Interior has appointed a commission of physicians and pharmacologists to prepare a new (seventh) edition. Among the new remedies to be recognised in this edition will be acid. pyrogallicum, amylium nitrosum, the bromine salts, antipyrinum, chrysarobinum, cocainum, hydrargyrum tannicum, cortex condurango and C. quebracho, lithium carbonic., mentholum, naphthalum β, naphthalinum, physostigminum salicyl. and sulf., thymolum, vaselinum, pilocarpinum hydrochl.

Vienna, May 22nd.

SCIENCE *EN FÊTE:* THE CONGRESS OF HYGIENE AT FLORENCE.

(*From our own Correspondent.*)

As if sensitive to the charge of a distinguished compatriot that "the Italians are a carnival people," the Florentines, amid the gay and imposing ceremonies that have made their city the resort of the artistic world for half the month of May, have introduced a scientific foil to the festive monotony, and in a "Congress of the Hygienic Societies of Italy" have at once relieved and heightened the enjoyment of the brilliant commemoration of Rossini and Donatello, of the historic *cortège* and tournament, and of the crowning solemnity of all—the unveiling of the façade of their glorious cathedral, the Santa Maria del Fiore. On Sunday, the 8th, in the Hall of the Istituto di Studii Superiori, the sanitary associations of the peninsula held their first Congress, and its promoters have every reason to be

Digitized by Google

gratified with the success they have earned. The hall itself, almost severe in its purely academic aspect, was adorned with the insignia of the leading hygienic societies of Italy—those of Brescia, Padua, Turin, Palermo, and Florence herself being conspicuous in the *trofeo*. A numerous and distinguished audience, including many ladies, more than filled it, as the President, Professor Paoli, opened the proceedings, indicating the signal services vouchsafed to the common weal by a sound and well-organised hygiene, and dwelling on the advances Italy has yet to make if she intends to assume her proper place in the State system of Europe. The usual congratulatory speeches and telegrams having been heard from the various representatives of the Government and of the learned societies, the audience rose to visit the "Esposizione d'Igiene"—a splendid assortment of sanitary apparatus and appliances, for which the spacious rooms of the Palazzo Fenzi had been hospitably thrown open. Much interest was taken in the mechanism of Professor G. Koster for the analysis of atmospheric air, a series of experiments being performed to illustrate its efficacy; while attention was equally attracted by the various systems of domestic convenience, from latrines to filters, devised by Italian officers of health.

In the afternoon sitting Professor G. Pacchiotti, who represented Turin, read an elaborate paper on the "Vaccinazione Anti-rabica" of Pasteur, in which he described the methods pursued by the French pathologist, reviewed the results, favourable and unfavourable, on the patients, and concluded by giving a guarded estimate of the system, maintaining that on the whole the good achieved was more than the risk incurred. An animated and discursive conversation ensued, in which Professors Ruata, Calovolo, and Luciani took the chief part.

Monday's proceedings included a discussion of the principal clauses of the New Code of Public Hygiene submitted to the Senate of the kingdom by the Prime Minister Depretis; after which the topics ranged from Italian sanitation in general to that of Florence in particular, and concluded with an interesting conference on the dispensary doctors of Italy, their qualifications and responsibilities, and the need for a higher remuneration of their services, especially in the remoter communes. The demand for a Minister of Public Health was urgently represented by the *conferenziere*, Dr. Benizzardi of Brescia, and the discussion received important contributions from Dr. Faralli of Florence and Professor Pacchiotti, the latter urging the claims of duly qualified lady doctors on the recognition of the State, and arguing that their possession of a diploma in medicine or surgery entitled them to the same offices and remuneration as similarly qualified men. The "Free Exercise of Pharmacy" was another keenly canvassed topic, ending in an almost unanimous consensus in favour of the exclusive rights of the pharmacists. In the evening a great banquet was held in the Sala Cornelio, at which a series of toasts, all tending to the fraternisation of the hygienic societies throughout the peninsula, were eloquently given and heartily acknowledged.

On the 10th, Dr. Bonizzardi, representing Padua, opened the day's business by demonstrating a method of his own for "The Easy Distinguishing of the Carcases of Animals dead from Epizootic Disease." He was followed by Dr. Busi, representing Palermo, on "Cremation as practised in Florence," and by Professor George Koster on the "Carbonic Acid of the Soil and Air of Florence;" after which a visit to Professor Koster's laboratory and observatory and to the Ophthalmological Clinique of Professor Paoli (President of the Congress) closed the proceedings for the forenoon. In the afternoon interesting papers were read by Dr. d'Ancona on "Rural Dwellings"; Dr. Bonizzardi on the "Drainage of Cities"; and by Dr. A. Bianchi on the "Selection of Troops for Service in Tropical Africa." This last led to a very keen discussion, in which Professor Pacchiotti took an able part. "Orders of the day" (as is usual in continental congresses) were thereafter moved and carried, and with a few appropriate remarks Professor Paoli declared the Congress dissolved—the second to be held at Brescia in the autumn of 1888.

THE VACCINATION ACTS.—The Gloucester Board of Guardians has, after a long discussion, decided, by 20 votes to 18, that nineteen persons who were reported for not having their children vaccinated should not be prosecuted, and that in future the vaccination officers shall not take proceedings in case of default without the direct sanction of the board.

Obituary.

JAMES TROUTBECK, M.B.

WE recorded last week the death of this gentleman, who was stricken down by pneumonia when apparently enjoying most robust health. James Troutbeck was a Cumberland boy, and as such was educated at Appleby Grammar School. After completing his school education there he commenced his medical studies at the Edinburgh Infirmary, and supplemented them by a great deal of work at the Carlisle Infirmary for three years. Here he was a great favourite with all; his kindness and gentleness endeared him to the patients, and his diligence and cheerful disposition made him an excellent servant of the institution. He subsequently came south and entered upon general practice at Bushey, and for some years worked laboriously at it. Leaving there, he recently took a practice at Finsbury-park. On Saturday, May 14th, he was in his usual health and retired to bed early. During the night he was seized with severe pain in the chest, and remained in-doors on a couch all Sunday. On the Monday he went into the City and saw his solicitor, and then consulted a surgical friend under the impression he had injured his ribs. It was found, however, that there was pneumonic consolidation of his left lung, and from his general condition grave fears were entertained, which were only too quickly realised; for during the next night he became unconscious and died at midday on Tuesday. His frank generous nature and his unvarying kindness had endeared him to a large circle of patients and friends.

KARL FRIEDLÄNDER.

AT Meran, in the Austrian Tyrol, in his fortieth year, has just died this able pathologist, leaving behind him a high reputation for what he did, and a still higher one for what he was expected to do. Beyond the strictly scientific "inner circle" he was little known; he was never in professional practice; he was a pathological anatomist pure and simple. A native of Brieg, in Silesia, he graduated as Doctor in Medicine in 1869. In 1874 he was assistant in the Pathologico-Anatomical Institute at Strasburg under Professor Friedrich von Recklinghausen—a post which he held for five years. In 1879 he removed to Berlin, where, in the Friedrichshain Hospital, he filled the modest position of assistant superintendent of post-mortem examinations. In the academic scale he never rose higher than a *privat docent*, and only a few months ago obtained the title of Professor, without, however, an official chair. He published from time to time the results of his investigations, his best known book being his "Mikroskopische Technik," a favourite manual with the beginner and even the proficient in microscopy. His other publications include "Researches on Local Tuberculosis" (1873); on "Lupus" (1874); on "Epithelioma and Carcinoma" (1877); and on "Hypertrophy of the Heart" (1881). In the recent investigations into micro-organisms he took an energetic part, his special contribution to the subject being his discovery of a micrococcus, for which he claimed a distinct pathological *rôle* in pneumonia, and which he first described in Virchow's *Archiv*. (1882). This minute germ integer is now referred to in the nomenclature of bacteriology as "Friedländer's coccus." In the fortnightly *Fortschritte der Medicin* he continued his microscopic work with equal energy and ability, and raised that periodical (published by Fischer, in Berlin) to the front rank among German scientific journals. The last number was published the day after its editor's death, which is announced by a few touching words of regret by Drs. Fürbringer, Hahn, Gottstein, and Kornfeld. *Multis ille bonis flebilis occidit.*

SAMUEL R. MOREWOOD, A.B., M.B. (T.C.D.).

WE regret to have to announce the death of this gentleman, which took place on May 26th after a short illness. Mr. Morewood for the past eight years has been medical officer of the Dispensary, Draperstown, co. Derry, and medical attendant of the constabulary. Mr. Morewood was a licentiate of the Royal College of Surgeons of Ireland

Digitized by Google

and a graduate in Arts and in Medicine of Trinity College, Dublin. He succeeded his father, who for thirty-two years was medical officer in Draperstown, and it is worthy of note that the same appointment was held by his grandfather for a period of twenty-seven years, so that for the greater part of a century members of the family have been in practice in Draperstown. Mr. Morewood's death, occurring at an early age (thirty-five), has caused very deep sorrow in the neighbourhood where his family have been so long held in the highest respect, and universal sympathy is felt for Mrs. Morewood and the members of his family. The funeral took place on Wednesday.

THE SERVICES.

Deputy Surgeon-General D. A. C. Fraser, M.B., the Principal Medical Officer of the South-Eastern District, has joined the Southern District for duty at the Royal Victoria Hospital, Netley, in succession to Surgeon-General W. S. Murray, whose appointment to Egypt we noticed last week.

Deputy Surgeon-General T. Tarrant, M.D., has handed over his charge at Bangalore and joined in Madras for duty.

ARTILLERY VOLUNTEERS.—3rd Volunteer (Duke of Cornwall's) Brigade, Western Division, Royal Artillery: John Quick, Gent., to be Acting Surgeon (dated May 21st, 1887).—1st Forfarshire: Robert Soutar, M.B., to be Acting Surgeon (dated May 21st, 1887).—1st Dorsetshire: Surgeon C. W. Parkinson resigns his commission; also is granted the honorary rank of Surgeon-Major, and is permitted to continue to wear the uniform of the corps on his retirement (dated May 21st, 1887).—5th Durham: Richard Brown, M.B., to be Acting Surgeon (dated May 21st, 1887).

Medical News.

COLLEGE OF PHYSICIANS IN IRELAND.—At the May examinations the following obtained licences in Medicine and Midwifery of the College:—

MEDICINE.—John Theodore Abbott, Alfred William Bewley, William Grounds Booth, Charles Edward Boyce, William Mitchell Branson, Thomas E. Burrowes, Frederick Norris Burwell, Harry Cartmell, Edward Joseph Cotton, Charles Edward Dawson, Robert Harper Dickson, William Dunbar, Julius Martin Ehrhardt, Cornelius Gerald Fitzgerald, Robert Alexander Flynn, Arthur Goff, William Robert Graves, Henry Bertram Greene, Robert William Harley, John G. Harries, Joseph Thomas Harty, John Henry Lister, George John Lough, Charles John Lyons, William McGeagh, James Magauran, James Hastings Morgan, Oliver Norris, Joseph Edward O'Meara, Andrew William Orr, Pierce Hugh Power, Hugh Roberts, Henry Harlow Sales, Harry Paynter Sloggett, John Edwin Slott, Harry William Smith, Timothy Thaddeus Teahan, George Thorpe, John Westwood, and Thomas Owen Williams.

MIDWIFERY.—John Theodore Abbott, William Grounds Booth, William Mitchell Branson, Harry Carmel, Robert Harper Dickson, Cornelius Gerald Fitzgerald, Robert Alexander Flynn, Arthur Goff, William Robert Graves, Joseph Thomas Harty, George John Lough, Charles John Lyons, Arthur Kennedy Mc Cutcheon, James Magauran, James Hastings Morgan, Oliver Norris, Harry Paynter Sloggett, John Edwin Slott, Harry William Smith, and Thomas Owen Williams.

SOCIETY OF APOTHECARIES.—The following gentlemen, having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates entitling them to practise as Licentiates of the Society on May 19th:—

Baxendell, Arthur, Rose Hill, Denton, Lancs.
Clark, Percy John, Margaret-street.
Cockerton, Herbert, St. George's Hospital.
Crowther, Astley Brodie, Laurel Bank, Luddenden, Manchester.
Date, W. Horton, St. Leonard's-place, Moseley, Birmingham.
Elias, James. Essex-road, Sale, Manchester.
Ewbank, William Withers, Hilgrove-road, Hampstead.
Wood, Frederic Charles, Hutton, Brentwood, Essex.

KING'S COLLEGE HOSPITAL.—The annual festival dinner in connexion with this Hospital was held on the 23rd inst., the Lord Mayor presiding, when a list of donations amounting to £1786 was announced by the secretary.

METROPOLITAN CONVALESCENT INSTITUTION.—By the permission of the Duke of Westminster a meeting in support of the interests of this institution was held at Grosvenor House on the 23rd inst. During the forty-seven years in which the charity has been in active operation more than 100,000 patients have been admitted to its benefits, the number last year being 4500.

THE Hospital Sunday collection at West Hartlepool was held on the 22nd inst.

VICTORIA HOSPITAL, BOURNEMOUTH.—At a meeting of the Hospital Committee a few days since it was announced that the subscriptions to the fund being raised for the erection of a hospital in celebration of the Queen's Jubilee had amounted to about £5000, and there was a like sum available for the same purpose from the old Dispensary Committee.

THE sum of £1000 having been offered by Mr. John Geddes towards the building of a new infirmary for Southport, a committee has been appointed to report upon the character, convenience, and structural arrangement of the present infirmary, which is said to be very inadequate to the demands made upon it.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—At the children's service on the 22nd inst. at Berkeley Chapel, Mayfair, the offertory, which amounted to considerably over £100, was collected on behalf of the children's Jubilee tribute for the erection of a new wing to this institution, of which Her Majesty is patron.

AT the forty-second annual meeting of the governors of and subscribers to the Birmingham and Midland Ear and Throat Hospital on the 23rd inst., it was reported that during the past year the income had amounted to £615, a sum which exceeded the expenditure by £129. The total number of cases registered at the hospital during the year was 3243.

DEVON AND EXETER HOSPITAL.—At the annual meeting of the governors of this institution, on the 19th inst., it was reported that during the year 1391 in-patients and 1932 out-patients had been treated. The ordinary income amounted to £7159, as compared with £7252 for the previous year, and the expenditure to £7908, as compared with £8106.

IN an action recently brought in the Loughborough County Court by two medical practitioners for the recovery of fees for professional attendance, the question of the reasonableness of the charges was submitted to Dr. Banfield of Leicester and Dr. Paul of Loughborough. The arbitrators ruled that the charges generally were exceedingly moderate, and one or two items having been struck out, judgment was accordingly given for the plaintiffs.

HOSPITAL FOR EPILEPSY AND PARALYSIS, REGENT'S PARK.—At St. George's Hall on Thursday evening, in aid of this hospital, a grand variety entertainment was given. Not the least interesting part of the varied programme was a gavotte, danced, in costumes of the period, by four ladies and four gentlemen. The entertainment was the first of a series which the friends of the hospital are promoting, with the object of raising a fund of £2500 for the purchase of the lease and the extinction of the debt with which the hospital has for some years been burdened. The hall was well filled, and the performances much applauded.

THE BRITISH MEDICAL TEMPERANCE ASSOCIATION.—The eleventh annual meeting of the British Medical Temperance Association was held at 11, Chandos-street, Cavendish-square, on Tuesday last; in the unavoidable absence of the President, Dr. Norman Kerr took the chair. The annual report stated that there are at present 350 members (all total abstainers), and 72 associates (abstaining medical students). Dr. Kerr read an account of the work of the Dalrymple Home for Inebriates since its establishment three years and a half ago: 103 cases had been admitted, of whom 85 have been discharged, and of these 36 are known to have done well. Dr. Walter Pearce read a paper on a case of acute cardiac dilatation due to alcohol. Dr. J. J. Ridge also showed experiments proving that quantities of alcohol under 2 per cent. promote the growth of bacteria in decomposing fluids, while the same quantities had been proved to be injurious to the growth of constructive protoplasm. — The annual meeting of the Central Irish Branch of the Association will be held in the Royal College of Surgeons, Dublin, on Tuesday, June 7th, at 4.30 P.M. The chair will be taken by the President of the Branch, Deputy Surgeon-General F. L. G. Gunn. Brigade Surgeon F. E. McFarland (President of the North of Ireland Branch), Dr. T. Collins, Dr. Lunn, Mr. R. Morton, F.R.C.S., and Mr. Learson will speak. The meeting is open to all members of the medical profession

LONDON HOSPITAL.—The ceremony of opening the Nursing Home and new library and other college buildings at this hospital was performed on the 21st inst. by the Prince and Princess of Wales, in the presence of a large and influential assembly.

THE Association for Preventing the Adulteration of Butter in Amsterdam has offered a prize of 1000 florins for the best means of detecting any foreign elements in natural butter made from the milk of the cow.

TOTTENHAM HOSPITAL.—The new wing (Samuel Morley Memorial Wing) of the above institution will be formally opened by the Princess of Wales at 3 o'clock this day (Saturday). This recently completed part of the hospital contains two children's wards, with fourteen cots each; sisters' dining-room; on the first floor, wards for paying patients in separate rooms, and "cubicals"; on the second floor, the operating room, which is reached by a hydraulic lift.

PARKES MUSEUM.—On June 1st and two succeeding Wednesdays, Dr. B. W. Richardson will deliver a course of lectures at the Museum, Margaret-street, on the Medical and Scientific Aspects of the Temperance Question. A very successful series of sanitary demonstrations to the medical profession has just been held in the Museum. The closing demonstration was given on the 23rd inst. by Mr. Percival Gordon Smith, of the Local Government Board, which related principally to the construction and ventilation of houses. On the 19th inst. a lecture was delivered by Major Jamarock Flower, C.E., on "The River Lea," in which he gave a description of the geology of the watershed area and of the navigation of the river from the Danish epoch till the present time.

THE FRENCH HOSPITAL.—The Prince of Wales was present on the 23rd inst. at an assault-of-arms at Willis's Rooms, given in aid of this institution. In the twenty years that the hospital has been open it has given relief to 1400 in-patients and over 100,000 out-patents. A new building, to accommodate double the number of patients, is to be erected shortly in Shaftesbury-avenue, and to this the Queen has given her patronage and a handsome subscription to the building fund. The entertainment on the 23rd was under the patronage of M. Waddington, the French Ambassador, and the company present included many of the leading French and Italian residents in London.

ROYAL UNIVERSITY OF IRELAND.—The following Honours have been awarded to candidates at the recent examinations of the University:—Second Examination in Medicine: Second Honours, Eleonora Lilian Fleury and Thomas Jones; Second Class Exhibition (£20), Eleonora Lilian Fleury. M. B. Degree Examination: First Honours, Ambrose Edward Birmingham; Second Honours, Edmond Joseph M'Weeny and William Westropp White. First Class Exhibition (£50), Ambrose Edward Ignatius Birmingham; Second Class Exhibition (£25), E. J. M'Weeney. M.Ch. Degree Examination: First Honours, John Wallace Watson; Second Honours, William Baird M'Quitty. M. A. O. Degree Examination: First Honours, William Westropp White and William Baird M'Quitty; Second Honours, Eaton William Waters, Edmond Joseph M'Weeney, and Jerome Barry. Doctor of Medicine: Second Honours, W. W. White. Bachelor of Medicine: First Honours, Ambrose Edward Ignatius Birmingham; Second Honours, E. J. M'Weeney. Master of Surgery: First Honours, J. W. Watson; Second Honours, W. B. M'Quitty. Master of Obstetrics: Honours, 1st Class, W. W. White and W. B. M'Quitty; Second Class, E. W. Waters, E. J. M'Weeney, and Jerome Barry.

THE LEVEE.—At a levée held on the 21st inst. at St. James's Palace by His Royal Highness the Prince of Wales on behalf of Her Majesty, the following amongst other presentations were made:—Surgeon J. F. Henry Bottrell, Volunteer Medical Staff Corps; Surgeon-Major George R. Barnes, 3rd Surrey Rifle Volunteers; Surgeon Robert Hippisley Cox, Coldstream Guards; Surgeon Herbert Collier, M.D., Royal Naval Artillery Volunteers; Surgeon William Collingridge, M.D., Volunteer Medical Staff Corps; Staff Surgeon A. G. Delmege, on appointment to Royal yacht *Osborne*; Surgeon A. P. H. Griffiths, Medical Staff, on his return from active service; Dr. J. de Burgh Griffith, of Melbourne; Surgeon Charles H. Hartt, Volunteer Medical Staff Corps; Surgeon Henry St. George Standish Hore, Medical Staff; Hon. Surgeon Edmund Distin-Maddick, Royal Naval Artillery Volunteers; Mr. Alexander O. Mackellar, chief surgeon to the Metropolitan Police Force; Surgeon George Hutchinson Milnes, R.N.; Inspector-General D. M'Ewan, M.D., R.N., on promotion and appointment as Honorary Physician to the Queen; Deputy Inspector-General H. F. Norbury, C.B., R.N., on promotion; Surgeon Herbert Innes Pocock, Medical Staff; Dr. Smith, Vice-President of the Royal College of Surgeons of Edinburgh and Surgeon Dentist to the Queen in Scotland; and Sir William Stokes, President of the Royal College of Surgeons of Ireland. Amongst those present at the levée were the following members of the medical profession:—Drs. M. Baines, Brodie, H. M. Chester, W. M. Collins, Fleming, Ralph Gooding, Lowe, William Moore, Minter, J. D. Macdonald, Poore, W. S. Playfair, Henry J. Strong, Quain, Mark Tanner, Thorne Thorne, George Wilks, Shapurji Aspaniarji Kapádiá, Rastamji Dhanjibhai Sethna, and Mr. Navoroji Manekji.

VICTORIA HOSPITAL FOR CHILDREN.—The twenty-first annual Court of Governors of this institution at Chelsea was held on the 18th inst. Mr. Martin R. Smith, the chairman, remarked that the new out-patients' wing had been completed nearly a twelvemonth, and that about 38,000 children had been treated during the past year.

THE offertory at the special jubilee service held at St. Margaret's Church, Westminster, on the 22nd inst., which has been forwarded to the treasurer of the Westminster Hospital, amounted to £123.

POPLAR HOSPITAL FOR ACCIDENTS.—The thirty-second annual festival in aid of the funds of this institution was held on the 20th inst., Mr. Sydney Buxton, M.P., presiding. The committee desire to extend the Samaritan Fund for assisting patients who have left the hospital and require medical appliances, and also to establish in connexion with the hospital convalescent homes where patients can be sent. They are anxious, too, if possible, to obtain sufficient funds to sever the in-patient department from that for out-patients. At present, in consequence of insufficient accommodation, the out-patients have to be seen in the basement of the building. Over 9000 patients were treated during last year, the number having nearly doubled in five years. During the evening subscriptions amounting to £1405 were announced by the secretary.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual general meeting of this Society was held at Berners-street on May 18th, Sir James Paget, Bart., President, in the chair. The annual report for 1886 was read by the secretary, from which it appeared that the number of members was 343 (twenty less than in 1885); only five new members had been elected, sixteen had died, and nine resigned or ceased to be members. The Society had lost two vice-presidents during the year by the deaths of Mr. Cooper Forster and Dr. Harvey Kempton Owen. The number of widows receiving grants was sixty-four—the same as in 1885; but the number of orphans had been reduced from nine to six, and there were three orphans receiving grants from the Copeland Fund. Five widows had been elected and one orphan. Five widows had died or become ineligible for further assistance, and three orphans had ceased to receive relief, having reached the age of sixteen. The amount distributed in grants had been £2750, and the expenses had been £243. Owing to the want of funds the directors had not been able to make any present to the widows and orphans last Christmas. Two legacies had been received—one of £50, from the executors of Miss Anne Lyne, per Dr. Stokes; another of £300, from Dr. Harvey K. Owen, V.P. The funded property had been increased by the purchase of £146 Metropolitan Consolidated Stock. Mr. Mould was elected a vice-president in the place of Dr. Iliff, deceased, and the following gentlemen were chosen directors in the place of the six senior, who retired by rotation—viz., Dr. Birkett, Dr. H. M. Duncan, Mr. Langton, Dr. J. M. Bright, Dr. F. de Havilland Hall, and Mr. Malcolm Morris; and Mr. Ware, Dr. Quain, Dr. John Clarke, and Mr. Fuller were elected trustees of all the funded property of the Society. A special grant of £26 was made to one widow. Votes of thanks to the editors of the medical journals were carried unanimously, for their kindness in assisting in making known the objects of the Society. It was resolved that the centenary of the Society should be celebrated next year by a dinner. A vote of thanks to the chairman closed the proceedings.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BAILEY, T. RIDLEY, M.B.Ed., has been reappointed Medical Officer of Health to the Bilston Union.

BISHOP, WILLIAM, M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Fifth District of the Bridge Union.

BUTTER, JOHN KERR, M.D., C.M.Aber., has been appointed Medical Officer for the Cannock District of the Cannock Union.

CANT, WILLIAM EDMUND, M.D., F.R.C.S., has been appointed Assistant Surgeon to the Central London Ophthalmic Hospital.

CARLESS, ALBERT, M.B., has been appointed Ophthalmic Clinical Assistant to King's College Hospital.

COX, A. H. LISSANT, M.R.C.S., L.R.C.P., has been appointed House-Surgeon to King's College Hospital.

GALLOWAY, WALTER, L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Birtley District of the Chester-le-Street Union.

HENSLEY, A. E., M.R.C.S., L.S.A., has been appointed Assistant House-Physician to King's College Hospital.

JEPSON, EDWARD CANE, F.R.C.S.Eng., L.S.A., has been appointed Medical Officer to the Durham Union Workhouse, vice Boyd, resigned.

KERR, WILLIAM SMITH, M.D.Glas., L.R.C.S.Ed. (and not James Kerr, M.B., C.M.Ed., as stated in our last issue), has been re-elected Surgeon to the Dumfries and Galloway Royal Infirmary.

LYON, THOMAS M. M., M.B., C.M.Ed., has been appointed Medical Officer for the Ford District of the Glendale Union.

MACNAB, ALLAN J., M.R.C.S., L.R.C.P., has been appointed House-Surgeon to King's College Hospital.

MAIR, R. S., M.St.And., F.R.C.S.Ed., has been appointed Physician to his Highness Prince Malcom Khan and the Persian Embassy, vice Vincent Ambler, deceased.

MARIETTE, ERNEST P.A., M.R.C.S., L.S.A., has been appointed House-Accoucheur to King's College Hospital.

OWEN, J. V., M.R.C.S., L.S.A., has been appointed House-Surgeon to King's College Hospital.

PEDLEY, R. DENISON, L.D.S., M.R.C.S., has been appointed Assistant Dental Surgeon to the National Dental Hospital, Great Portland-street, W.

PHILLIPS, JOHN, M.R.C.S., L.S.A., has been appointed Medical Officer for the Llanboldy District of the Narberth Union.

REYNOLDS, H. S., L.R.C.P., F.R.C.S.Ed., has been appointed Medical Officer for the Codnor-park District of the Basford Union.

SANDERS, CHARLES, M.B.Lond., M.R.C.S., has been appointed Medical Officer of Health for the Borough of West Ham, vice Deane, resigned.

SKELLY, WILLIAM, B.A., M.D. Q.U.I., L.R.C.S.Ed., has been appointed Medical Officer for the East District of the Poplar Union.

STEPHENS, R. J., L.S.A., has been appointed Assistant House-Accoucheur to King's College Hospital.

WHEATLEY, JAMES, M.R.C.S., L.S.A., has been appointed House-Physician to King's College Hospital.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the principal Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

ANCOATS HOSPITAL, Manchester.—Junior Visiting Surgeon. Salary £50 per annum, with board and laundry service.

CAMBERWELL PROVIDENT DISPENSARY, S.E.—Four Medical Officers.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Anæsthetist.

EASTBOURNE UNION.—District Medical Officer. Salary £85 per annum, with the usual extra fees.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Registrar and Chloroformist. Salary £30 per annum, with additional £20 if the post is held for twelve months.

GROVE HALL, Bow, E. — Assistant Medical Officer to large private asylum. Salary at the rate of £120 during the first year; afterwards of £150. Board, lodging, and washing.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident Clinical Assistant.

Digitized by Google

ERPOOL NORTHERN HOSPITAL.—Assistant House-Surgeon. Salary £70 per annum, with residence and maintenance in the house.
TROPOLITAN FREE HOSPITAL, Kingsland-road, Shoreditch, E.—Dental Hospital.
LLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Senior Resident Medical Officer. Salary £60 per annum, with furnished apartments, board, attendance, and washing.—Junior Resident Medical Officer. Salary £30 per annum, and like accommodation.
BAR UNION, Essex.—Medical Officer and Public Vaccinator. Salary £75 per annum, with the extra medical fees prescribed by the Consolidated Orders of the Local Government Board and other additional charges in respect of lunacy and vaccination.
EN'S COLLEGE, Birmingham.—Co-Professor to share the duties of the Chair of Surgery.
YAL COLLEGE OF SURGEONS OF ENGLAND.—Professors and Lecturers.
YAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand, W.C.—House-Surgeon.
YAL UNITED HOSPITAL, Bath.—Resident Medical Officer. Salary £100 per annum, with board and lodging.
MARY'S HOSPITAL, Paddington, W.—Secretary. Salary £300 per annum, with board and residence, or £360 without.
IETY OF APOTHECARIES, London.—Twelve examiners.
INES UNION.—District Medical Officer. Salary £65 per annum, exclusive of the authorised fees for surgical and midwifery cases.
AMFORD HILL, STOKE NEWINGTON, &c., DISPENSARY.—Resident Medical Officer. Commencing salary £105 per annum, with an allowance of £50 for fuel and light.
YD VALE COLLIERY SICK AND ACCIDENT SOCIETY. Skelmersdale, Lancashire.—Medical man. Salary about £150 per annum.
TORIA HOSPITAL FOR CHILDREN, Queen's-road, Chelsea, S.W.—Resident Medical Officer. An honorarium of £20 for the first six months, and £30 for the second six months, will be given, and board and lodging in the hospital provided.
ITEHAVEN AND WEST CUMBERLAND INFIRMARY.—House-Surgeon. Salary £120 per annum, and £30 a year for dispensing, with furnished apartments and attendance.

Births, Marriages, and Deaths.

BIRTHS.

RER.—On the 21st inst., at Glenavon, Stoke Newington-common, N., the wife of Thomas Furze Clarke, M.R.C.S., of a daughter.
N.—On the 13th inst., at Churchill Court, Worcestershire, the wife of Ernest Harrold Fenn, Surgeon, Grenadier Guards, of a son.
.—On the 22nd inst., at Gay-street, Bath, the wife of Arthur H. W. Fox, M.B., F.R.C.P.E., of a daughter.
ERTSON.—On the 16th inst., at Roehampton, S.W., the wife of A. Milne Robertson, M.D., of a son.

MARRIAGES.

TLEY—FENWICK.—On the 21st inst., at the Cathedral, Newcastle-on-Tyne, by the Lord Bishop of the Diocese, assisted by Canon Lloyd and the Rev. G. Fenwick (brother of the bridge), William Crump Beatley, M.D., to Frances Mary, daughter of J. G. Fenwick, J.P., of Moorlands, Gosforth, Newcastle-on-Tyne.
DWOOD—MCCANN.—On the 20th ult., at St. Mary's Church, Aston, Roger Alan Birdwood, M.B.Camb., M.R.C.S., to Agnes, youngest daughter of the late Hugh McCann, of Birmingham.
LER—WACHER.—On the 19th inst., at the Parish Church, Herne, Walter Fowler, M.A., M.B., B.C.Cantab, F.R.C.S.Eng., to Alice, fifth daughter of William Wacher, Esq., of Eddington, Herne.
CHANT—SPARKE.—On the 14th inst., at the Parish Church, Mansfield, by the Rev. Canon Pavey, John Burrell, eldest son of the late John Marchant, of Hertford, Solicitor, to Marion Guyse, second daughter of Geo. Whitefield Sparke, M.R.C.S.
AR—EDMONDS.—On the 17th inst., at St. John's the Divine, Richmond, William Henderson Starr, M.R.C.S., L.R.C.P.Lond., Army Medical Staff, to Helena Mary, daughter of Henry Edmonds, of Kew.

DEATHS.

MIE.—On the 20th inst., at Stanhope-gardens, Queen's gate, S.W., Patrick Gammie, Surgeon-General, aged 73.
KESON.—On the 12th inst., at Balisera, India (of fever), W. Whiteside Paterson, M.B., C.M., M.R.C.S., youngest son of the late Andrew Paterson, of Carston, Ayr, in his 25th year. (By telegram.)
ERS.—On the 13th inst., at South Kensington, William Hinds Rogers, M.R.C.S., of Yealmpton, South Devon, aged 64.
ELL.—On the 30th ult. (of septicæmia), at Lahore, India, Ella Mary Tickell, aged 23, eldest daughter of Henry J. Back, L.R.C.P., M.R.C.S., of Clapton-common, London, the beloved wife of Charles Tickell, Esq., C.S., of Mardan, Punjab, India, youngest son of the late Lieutenant-General Tickell, C.B., of Cheltenham. Deeply lamented.
EN.—On the 12th inst., at The Limes, Wigton, Cumberland, Robert Tiffen, M.D., aged 63; also on the 15th inst., Ann, his wife, aged 59.
NER.—On the 18th inst., very suddenly, Thomas Aubrey Turner, M.R.C.S.E., of 8, Alexandra-road, Finsbury-park, eldest son of the late Rev. T. B. Turner, of Kingston, Jamaica, aged 42. R.I.P.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

BLENNORRHAGIA.

R. J. M. (Belfast).—A succinct study on the etiology and treatment of this disorder is given by Dr. Ulisse Malusardi in the *Gazzetta Medica di Roma* of May 1st. His conclusions, set forth as the result of special clinical experience, are these:—1. Gonorrhœa (or blennorrhagia, as he prefers to call it) is a specific local affection, the principle of which consists invariably in the presence of a parasite (*gonococcus*) in the secretion. 2. This infective principle of blennorrhagia with its parasitic basis must be constantly treated from the beginning with antiseptic remedies. 3. Injections of hydrochlorate of cocaine are the sovereign antidote to nocturnal erection or chordee. 4. The use of warm baths, even prolonged, is not contra-indicated, as it materially allays the patient's sufferings and facilitates resolution. 5. Incomparably the most powerful and least hazardous antiseptic is corrosive sublimate in doses increasing from 0·5 per cent. to 1 per cent., after the action of iodoform has been proved to be inefficacious. 6. In the local sequelæ of blennorrhagia advantage is often derived from the use of the sulphate of zinc, combined with that of corrosive sublimate. Tobacco is not forbidden in such cases by Dr. Malusardi, who, on the contrary, agrees with the French specialists in "never having repented of allowing its use."

M.D.—The method referred to is not one to be commended. The proper course would have been for the gentleman to send a card to each of his patients announcing the removal.

J. M. L. is referred to a general notice at the head of this column.

NON-SACCHARINE ALCOHOLIC DRINKS.

To the Editors of THE LANCET.

SIRS,—It occurs to me that you may by an annotation or a short article make known a want and get it supplied. The want I refer to is an alcoholic drink which does not contain sugar. This is especially needed for diabetic and gouty persons; and, except unsweetened gin, which is unpleasant to many, I know of no form of alcohol which is free from sugar. Unsweetened whisky would be especially valuable, and it is almost impossible to get any. Sugar-candy, or sugar in some form, is added to nearly all whisky, to give it roundness and mellowness. Brandy contains a good deal, and even claret a small quantity. I am afraid my letter alone will do no good; but if you recognise the want and make it known it will cease to exist.

Believe me, Sirs, yours truly,

May 21st, 1887. F.R.C.S.

LEECHES.

J. S. C. (Leeds).—The first to employ leeches was Themison, a physician of Laodicea and contemporary of Pompey. He was also the founder of the sect of the Methodici, and is often cited as an authority, especially by Caelius Aurelianus. Dr. Greenhill distinguishes him from the Themison satirised by Juvenal (x., 221), who, it being then the custom with artists of every kind to assume the name of celebrities in the same walk, no doubt called himself after his distinguished predecessor. This assumption of names is one of the many difficulties besetting the historian of ancient medicine.

W. P. F.—We fear that the universities named are, under the circumstances, all practically closed to our correspondent. Cases such as his show very clearly and very painfully the disadvantages under which the London student at present labours.

J. C. should consult one of the old-established firms of surgical instrument makers.

Mr. Larchin.—Dr. Murrell's book.

THE POLLUTION OF THE THAMES.

To the Editors of THE LANCET.

SIR,—The Metropolitan Board of Works profess that at last they are about to run a satisfactory effluent into the Thames. They carefully avoid, however, to state on what grounds they consider it satisfactory, and it is only by supplementing the figures which they have published by one or two more which their chemist, Mr. Dibdin, has communicated to the Institution of Civil Engineers, that it is possible to ascertain definitively what they now propose to do. Mr. Dibdin states the strength of the sewage now turned into the Thames at 87 grains of foreign matter per gallon. Captain Calver stated it in his report at 265·50 grains, at two hours after high-water, and 189·0 grains at two hours before low water. But let us take Mr. Dibdin's figures, and also his statement that the "pressed cake," which is the most unobjectionable form into which the matter removed from the sewage is converted, contains 58 per cent. of water. It is easy on these data to calculate that the treatment described in the recent report of the Finance Committee of the Board of Works removes 31 grains per gallon of foreign matter from the sewage, and and thus turns into the Thames an effluent containing 56 grains of impurity per gallon, which is, in fact, only a very slightly diluted sewage. Indeed, out of 20 grains of organic matter in solution only 2·6 grains are removed by precipitation. As the result of this very minute improvement, 30 tons 16 cwt. of foul sludge are produced from each million gallons of sewage. Tanks are erected, at a cost of £106,000 for the north of the river alone, to allow this sludge to subside; by which process it is reduced to 18 tons 6 cwt. of drier and thicker sludge. It is this product which it is now proposed to boat away to sea. Its amount, on a daily outflow of 160,000,000 gallons of sewage, is 2928 tons. The total solid matter removed from the sewage is under two tons per million gallons. This is increased by the method now accepted by fifteenfold, and by more than ninefold after the cost of a second subsidence. If this is satisfactory to the Metropolitan Board of Works, the satisfaction will hardly be shared by the frequenters of the Thames, or by the ratepayers of London. I am, Sirs, yours obediently,

May 20th, 1887. M.INST.C.E.

A DOCTOR'S REAL HOLIDAY.

To the Editors of THE LANCET.

SIRS,—Any middle-aged practitioner must have met with many men who have gone on for years practising until they have at last broken down from worry, work, and *ennui*. Why do not some of our worn and weary brethren copy the clergy, and go far away for three or six months' complete change? I have known more than one doctor work on till compelled to give up practice, and then linger on in misery to himself and a trouble to his friends through years of invalidism. A local clergyman was worn and done up; he left for fourteen months, returning well. I have often known a clergyman go away for six months, and hundreds of the clergy, even in these days of poverty and anti-tithe agitation, go off for two months. But our medical brethren, who have so much worry and night-work, so few holidays, so little society, are just the men who cling to work till the last, and yet many doctors have good private means, and some have lucrative and easy enough practices in addition. There are hundreds of middle-aged and experienced men, who would do the kind of work I am alluding to. I am sure that a fee of fifty guineas would secure for three or four months a competent *locum tenens*, glad to look after a first-class practice and to do full justice to it. Such a course of action would add years to many a weary practitioner's life, and secure that holiday for him that he of all men most needs.

I am, Sirs, yours truly,

May, 1887. S. U. M.

NEW SOUTH WALES.

To the Editors of THE LANCET.

SIRS,—I shall feel much indebted to any of your readers who are conversant with New South Wales if they will give me any information as to the diseases which are most prevalent there. Also, if drugs and instruments are to be easily obtained at any of the large towns; or what drugs and surgical instruments it would be advisable to take out, and any other hints and suggestions will be thankfully received by,

Yours faithfully,

May 23rd, 1887. VIATOR.

"DR. PEACAN'S TREATMENT OF CHOLERA."

IN our issue of the 14th inst. we published an annotation on this subject. Our attention has since then been called to the fact that, excepting some surplusage in after-medication, Dr. Peacan's method of treatment of cholera is in principle, and also in practice, identical with the plan proposed some years ago, and commented on by us at the time, by Dr. Alexander Harkin of Belfast. To this latter observer, who in 1884 published a paper read by him in 1884 before the Ulster Medical Society, in which his theory of the causation and cure of the disease is expounded, must be ascribed the merit of originality, Dr. Peacan's success in cholera treatment being a striking proof of the soundness of Dr. Harkin's views tested in a different hemisphere.

Etiquette should receive the visit of the neighbour alluded to without prejudice. Time will show if his delay in calling arises from unfriendly or discourteous motives.

Surgeon will find in THE LANCET of Dec. 6th, 1884, p. 1030, a letter which will inform him on the points he mentions. Appeal should be made to the commissioners.

THE BROWN DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—We, the undersigned, crave your permission for a few remarks in connexion with the above case. Having allowed a fair time to elapse since attention was called to the matter by the letter of Dr. Bates, Dr. Broadbent, and Mr. Sydney Jones in your issue of April 9th, and finding only an inconsiderable response to the appeal, we think we might invite further notice to the case. Up to the present date the sum of only £20 9*s.* 6*d.* has been received, which goes a short way indeed towards defraying the law costs, amounting to over £160. Mr. Brown being personally known to us, we believe we can confidently state that he became involved in the matter through no indiscretion or imprudence on his part. Indeed, his position was one in which any member of our profession might find himself at any moment, and as he can ill afford to be at such a serious loss, we solicit help on his behalf. As we believe many of his professional brethren would contribute a small amount where they cannot spare much, we desire to make it known that we will gladly receive any contributions, however small, as it is apparent to us that if even a limited number of the medical practitioners of the country would each give half-a-crown, or even less, the whole sum required would be paid off many times over. In conclusion, we might say (should it be wished by those contributing) that the donors will be acknowledged without the amount being specified. Hoping we shall not make this appeal in vain, and thanking you for the interest you have shown in the matter and the courtesy you have extended to us.

We remain, Sirs, faithfully yours,

ROBEY & ROBEY, 129 & 143, St. John's-hill, New Wandsworth.
J. H. T. CONNOR, 49, St. John's-hill, S.W.
R. F. FRAZER, 185, Lavender-hill, S.W.
M. G. BIGGS, 101, Northcote-road, S.W.
MABYN READ, Clapham Common-gardens, S.W.
J. T. BOYD, 73, St. John's-hill, S.W.
JAMES E. LAWRENCE, East-hill, S.W.
T. A. IVES HOWELL, 14, High-street, Wandsworth, S.W.
G. STANLEY MURRAY, Meadow-side, Putney.
RICHD. R. W. ORAM, Cremyll, Wandsworth Common.
R. H. A. HUNTER, Clifton House, Battersea.

May 23rd, 1887.

To the Editors of THE LANCET.

SIRS,—Kindly insert the following:—Amount already acknowledged £19 8*s.* 6*d.*; Arthur Ives Howell, Esq., £1 1*s.*

I am, Sirs, yours faithfully,

G. STANLEY MURRAY, M.D.

23, Upper Richmond-road, Putney, May 23rd, 1887.

MEDICAL ATTENDANCE ON THE SICK POOR, NOT PAUPERS: A CORRECTION.

To the Editors of THE LANCET.

SIRS,—If "F. T. S." will kindly refer to an annotation in THE LANCET of April 23rd, he will find at p. 791 that you mention in your notice of my paper on the medical attendance of the sick poor: "One feature of Dr. Alderson's views is the suggestion of a graduated scale of payment varying from 6*s.* to 30*s.* per year for single persons, or 30*s.* to £6 per year for families;" and if "F. T. S." would refer to the original pamphlet (and I should be pleased to send him one), he would read at p. 9, "a patient whose income is £150 a year could easily pay out of it from £3 to £8 for medical attendance." There is no allusion to an income "of £312." Although at a much increased rate on the principle of health insurance, as I mentioned in my pamphlet on "The Wants of the General Practitioner," I would even attend patients of a much higher social position and of larger incomes. The £6 per week which has caused your correspondent "F. T. S." "some amusement" is a clerical error. What I meant to have written was that I was willing to attend a patient (with a family) for £6 per year, whose wages averaged £3 per week. I noticed this error directly I read my letter in print, but the mistake appeared to me so obvious that I did not care to trouble you by asking a correction, which I am now anxious to do, for it is this class, whose income is under £3 a year, that requires aid in providing medical skill when illness overtakes its members. I am, Sirs, your obedient servant,

May 21st, 1887. FRED. H. ALDERSON.

MEDICAL PRACTICE IN THE NEW WORLD.

To the Editors of THE LANCET.

IRS,—In the expectation that some one nearer home would be able to e the information asked for by "A Constant Reader" in your issue of rch 19th, I have refrained from writing; but as THE LANCET for ril 9th has just come to hand without anyone giving the desired ormation, I will endeavour to help him.

s regards the Western States, there are many good openings in them, in Washington Territory, Oregon, California, Colorado, &c. In all hem British diplomas entitle the holder to registration. Drugs can obtained with little or no difficulty in almost any part of the country. regards the climate, some sections of the country, as California and orado, suit certain cases of lung disease admirably. Near the coast the ct is bad on cases coming to the country, though natives of the place not suffer much from chest affections. In British Columbia, before mencing practice a new-comer must present himself before the dical Council, produce a degree from a recognised college or university, s an examination in all the primary and final branches, and pay a fee £20 and an annual fee of £2 10*s*. These regulations apply to all alike, mattter what qualification they hold. In this province, moreover, enings are rare, the proportion of doctors to population is about 1 to , while in some places, as Victoria and New Westminster, the pro- tion is as low as 1 to 600, or less. The climate is not particularly table for lung diseases, except some cases which do well in the untains. I am, Sirs, yours sincerely,

W. A. DE WOLF-SMITH, M.D.

New Westminster, British Columbia, April 26th, 1887.

G. T.—1. The holder of a real American or continental degree is warranted in using the title attaching to the degree on his plate, &c.; but t is not a sufficient title in cases of medical certificates. The mere se of it after other and recognised British titles is not necessarily llegal.—2. We know of no means of ascertaining whether any given erson is possessed of any degree which he professes to have than by nquiry of the authorities or inspection of the rolls of the university.

R.C.P. would probably obtain much of the information he desires by pplying to Messrs. Moore and Co., Houndsditch.

AN URGENT CASE.

To the Editors of THE LANCET.

SIRS,—About five years ago you were kind enough to allow the late . A. P. Stewart and myself to make an appeal in your columns for two lies, sisters, who have had to maintain for about twenty years their ther, Mr. Charles Gaffney, who practised at Buntingford before he s overtaken with insanity. The case is well known to the benevolent ieties of the profession, and has repeatedly been generously assisted them. But it still continues in all its hard facts. The brother has to maintained from home, and the sisters, to support him and them- ves, have to keep a boarding-house. Their increasing age and the rdness of the times have landed them in straits which I do not like to scribe; but they are still holding up. Their account of the help of ends, including some who had little to give them, is reviving reading. ey are extremely needy and equally deserving. I shall be pleased to the medium of any sums which any of your readers can spare for m, and to acknowledge the same in your columns.

I am, Sirs, your obedient servant,

5, Highbury-place, N., May, 1887. JAMES GREY GLOVER.

lagator (Norwich).—Dr. Pietro Canalis, assistant in the laboratory of general pathology in the University of Turin. His paper, entitled Contribution to the Study of the Development of the Experimental Pathology of the Supra-renal Capsules, with six Illustrations," was recently presented by Professor Bizzozero to the Royal Academy of Sciences of Turin, in the "Atti" of which it will shortly be published.

r. D. C. Trott.—It would be better, we think, to address the communication to the editor of the journal in which the correspondence referred to appeared.

Pierrepoint.—The letter is of the nature of an advertisement.

HERNIOTOMY IN YOUNG CHILDREN.

To the Editors of THE LANCET.

SIRS,—In your last issue, page 1029, Mr. Lionel Stretton reports a case which he successfully performed herniotomy in a child four weeks old, d states that he has "been unable to find any account of operation in young a child." A moment's reference to Sections 954:2 of the dical Digest and Appendix will point to a case by Mr. Macnamara in 79, aged three weeks, and to another by Mr. Hazlewood in 1884, also ed three weeks, both reported in your valuable journal.

I am, Sirs, obediently yours,

Boundary-rd., N.W., May 21st, 1887. RICHARD NEALE, M.D. Lond.

THREADWORM.

To the Editors of THE LANCET.

SIRS,—Will any of your readers kindly suggest a mode of treatment r an obstinate case of threadworm in an adult, all the usual remedies ving failed, including many changes of climate?

I am, Sirs, yours obediently,

May 17th, 1887. M.R.C.S., &c.

SWEATING OF THE FEET.

A Sufferer.—The question has been repeatedly noticed in our columns. The following is the reply made to a correspondent in our issue of July 7th, 1877, p. 37:—"The complaint is not easily cured. The patient in question should not walk so much as to induce these foot-sweats. Tonic doses of quinine with mineral acid and well-regulated dress should be recommended. Great relief is sometimes afforded by a foot-wash made by adding half an ounce of solution of subacetate of lead, diluted with water enough for a foot-bath. Hebra recommends an ointment composed of equal parts of lead plaster and linseed oil spread on linen, and wrapped round the feet, renewing the application every third day for nine days. Laced shoes are preferable to boots."

Dr. Ridley Bailey.—There are several good filters in the market, amongst which it is not easy to indicate the best. The ease with which the apparatus may be cleansed, and the efficiency of the filtering material, are of course the chief points to be kept in view in purchasing a filter.

Hertford.—We know of no other societies of the kind at present in existence than the one mentioned.

A WARNING.

To the Editors of THE LANCET.

SIRS,—I shall be glad if you will allow me through THE LANCET to warn my professional brethren that an impostor is going about soliciting alms representing himself to be Mr. Wm. Ashton Patchett, late of Shaw, and stating that he is a widower with two children, and entirely destitute. To confirm his statement he produces some original testimonials from Sir W. Roberts, Mr. H. Lund, &c., which were given to me when I was a candidate for a hospital appointment seventeen years ago, and which by some means he has obtained possession of. I have come to the conclusion that the scamp must be a man who acted as assistant to me for a few days some time ago, and who stole not only the testimonials, but a number of my medical books also. I am informed that in London he has only too successfully imposed upon several benevolent medical gentlemen. I hope this warning may nip in the bud the rascal's extortions. I am, Sirs, yours faithfully,

Shaw, May 18th, 1887. W. A. PATCHETT, M.R.C.S. Eng., L.S.A.

L.K.Q.C.P.I., L.M.—We are not prepared to recommend the particular steps to be taken; but it is obviously right that in public papers, posters, &c., there should be no misstatement, and our correspondent would be justified in objecting to the description and title given as inaccurate. In answer to the third question, our correspondent, with the qualifications mentioned, can recover in medical and midwifery cases, but not in surgical ones.

R.—Our correspondent should consult his legal adviser. A great deal might turn on the details of the course taken in the past by the respective parties.

INTESTINAL OBSTRUCTION CAUSED BY IMPACTED GALL-STONE.

To the Editors of THE LANCET.

SIRS,—In your issue of April 30th Dr. Allen reports a case of operation for intestinal obstruction caused by impacted gall-stone, and states that he can find no such case on record. I beg to refer him to a similar case published by me in THE LANCET for 1881. A previous case by Mr. Bryant is also on record. Both of these were fatal. I think also one or two cases have been published since, but do not remember the particulars of them.

I am, Sirs, yours truly,

Reigate, May 13th, 1887. J. WALTERS, M.B., &c.

CHRONIC RHEUMATIC ARTHRITIS.

To the Editors of THE LANCET.

SIRS,—Can any member of the profession kindly inform me what drug he has found most efficacious for relieving pain and promoting sleep in a case of chronic rheumatic arthritis? An elderly person has had this affection for the past two years, and now suffers a good deal at night from pain in the joints and sleeplessness. A great variety of medicines have been tried, including potass. iodid. and potass. bromid., but latterly with very little effect. Morphia cannot be given owing to the patient having a weak heart.—I am, Sirs, yours truly,

May 24th, 1887. MEDICUS.

Dr. Haddon (Melrose).—We shall be glad to receive the paper, and to give it our attention.

TREATMENT OF TÆNIA SOLIUM.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if you would insert this letter in your next issue, on the chance that some of your numerous readers might be able to help me. I have a patient suffering from tænia solium, and have tried all kinds of remedies, but fail to do more than get rid of small quantities. I have used kousso in full doses, extract of male fern, and pelleterin. Any hints would oblige.—I am, Sirs, yours very truly,

May, 1887. PUZZLED.

Medical Diary for the ensuing Week.

Monday, May 30.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

Tuesday, May 31.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.
ROYAL INSTITUTION.—3 P.M. Professor Victor Horsley: The Modern Physiology of the Brain and its Relation to the Mind.

Wednesday, June 1.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Mr. Lockwood, Dr. Bluett, Dr. Malins, and others.—Dr. Cullingworth: A case of Cesarean Section.—Dr. Champneys: On the Separation and Expulsion of the Membranes.—Dr. Walter Griffith: On Tubo-ovarian Cysts.

Thursday, June 2.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION.—3 P.M. Professor Dewar: The Chemistry of the Organic World.

Friday, June 3.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Mr. H. Percy Dunn will show the specimens which have been added to the Museum of the West London Hospital during the session.—Mr. F. Swinford Edwards: A collection of Urinary Calculi.—The President: An Hypertrophied Heart.—Dr. P. S. Abraham: Microscopical Sections of Ossification of the Cauda Equina.—Brigade-Surgeon W. Curran: Sketches of Aortic Aneurysm and Sarcoma of the Lung.—Dr. Bullock: A Skull from a case of Hereditary Syphilis.—Sir Andrew Clark: A Frequently Successful and Speedy Method of Treating Hay Fever.
ROYAL INSTITUTION.—9 P.M. Mr. David Gill: The Application of Photography to Astronomy.

Saturday, June 4.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION.—3 P.M. Prof. John W. Hales: Victorian literature.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months..... £0 16 3
To CHINA AND INDIA.....One Year 1 16 10
To THE CONTINENT, COLONIES, AND UNITED STATES ..... Ditto 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

Lectures
ON
INJURIES OF NERVES.

Delivered at the Royal College of Surgeons,

BY ANTHONY A. BOWLBY, F.R.C.S. ENG.,
SURGICAL REGISTRAR AND DEMONSTRATOR OF SURGICAL PATHOLOGY AT ST. BARTHOLOMEW'S HOSPITAL, HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS.

LECTURE III.

SYMPTOMS OF COMPLETE SECTION OF A NERVE TRUNK.

MR. PRESIDENT AND GENTLEMEN,—The symptoms of nerve injuries of all kinds have much in common, but considering that those caused by bruising, pressure, partial division, &c., possess some points of difference from cases of simple division, I shall at present treat of the latter alone.

The *pain* caused by division of a nerve trunk does not appear to be very severe, for, judging by the accounts of patients, no further pain than that caused by the skin wound seems to attract attention in at any rate the larger number of cases. Numbness and tingling frequently cause more anxiety than does the actual pain.

The *shock* following on an injury to a nerve trunk is not a very noticeable feature in patients met with in civil practice, though Mitchell records many cases of gunshot wounds in which it was present.

The *loss of muscular power* and of the *sense of touch* are symptoms of far greater import than either of the foregoing. With regard to the former, it may be said at once that the muscles supplied by the divided nerve become absolutely powerless, and remain so as long as the divided nerve ends continue ununited; their functions may be to a certain extent supplied by surrounding muscles, as insisted on by Létiévant, but they themselves undergo a rapid atrophy and degeneration, which is the cause of many deformities, and which affords a sure evidence of the injury that has been sustained.

Sensation may be affected in many ways; there may be loss of sense, of touch, of pain, of temperature, and of weight, anæsthesia, hyperæsthesia, and various abnormal sensations, such as pricking, tingling, numbness, &c.

The *thermal sense* is generally lost in proportion to the loss of the sense of touch and over the same area; in very many cases, however, in which complete anæsthesia is not present, there is no power to discriminate between heat and cold. The amount of loss may be easily determined by making the patient dip the fingers into water of different temperatures, or else by touching the skin of the affected part with some steel implement which has been heated to a certain degree in hot water.

The *anæsthesia* which follows nerve section is generally to the patient the most obvious result of the injury he has sustained, but the exact extent to which it is present requires an immense amount of time and care to estimate. The best mode of estimating the acuteness of the tactile sense in different parts of the body is to measure the distances at which the two points of a pair of compasses can be detected as such, but, in addition, the power of localisation must be duly noted. For general purposes it is best to try roughly to find the presence or absence of anæsthesia over a given area by means of lightly touching the skin with the point of a pencil or penholder, and then proceed to map out the exact amount of anæsthesia with a pair of compasses and a rule. The patient should always be placed in such a position that it is impossible for him to see the hand of the surgeon or the area which is under observation; he should not be allowed to move the finger or other part touched, for thereby the muscular sense comes to the aid and falsifies observations; the impact of the instrument used should be very light, for, as Létiévant has shown, a patient can frequently discern friction on an anæsthetic surface by means of vibrations carried by the tissues to surrounding healthy nerves. The distances at which the points of a pair of compasses can be detected as such have been given approximately by physiologists, but are almost valueless in testing the sensation of the hand of a working man, in whom the cuticle is so thickened and horny as to be insensible to slight contact of any kind. It must also be remembered that the distance at which the two points of the compasses can be distinguished varies according to whether they are applied in the long or transverse diameter of a digit.

The readiness with which a patient can recognise *friction* when applied to an anæsthetic finger requires more than a passing notice, for it is liable to become a very fertile source of deception. I have often seen the sensory power of a presumably anæsthetic area tested by rubbing the part with the finger while the patient's eyes were averted, and almost always with the result that the stimulus was correctly perceived, and that a returning sense of touch was diagnosed by the investigator. Such a conclusion is entirely erroneous, for, as Létiévant has pointed out, any person can perceive friction applied even to the finger of another person when held between the bases of two fingers of his own hand; i.e., the vibrations are conveyed to, and appreciated by the nerves of the surrounding digits. How much more must this be the case when, as in the case of median division, healthy nerves exist on the same finger to which the friction is applied. Friction should therefore never be used as a test of sensation. For the same reason, the part which is being examined should never be pushed, or thrust away from the position in which it lies. This, I think, needs no further explanation.

If, then, the parts supplied by the terminal branches the divided nerve be tested with every care, it will before quently found they are not completely anæsthetic even cases of complete section of the trunk. A careless examination in such a case might readily lead to the belief that the nerve had not been divided, and that such operative measures as might otherwise have been considered advisable were no longer necessary. The merit of first drawing attention to this condition is due to M. Richet, in a case observed by him in 1867, and since that date the theory of nerve "anastomosis" has been so largely accepted that some authors—e.g., Létiévant, Arloing, and Tripier, and others have applied it to explain symptoms, many of which were undoubtedly due to true regeneration. Now, in far the larger number of cases it becomes very difficult to say for certain whether the power of distinguishing touch is really due to regeneration or to nerve anastomosis, and only an examination of the divided ends can set the matter at rest. In others, where the section has been very recent, and the distance separating the upper from the lower end precludes the possibility of union, any tactile sense must be referred to the influence of nerve anastomosis. On the other hand, in many cases a careless examination will lead the surgeon to the conclusion that all sense of touch is absolutely lost, and that the part is completely anæsthetic; consequently, there are not a few who deny the presence of any tactile sense in the paralysed part, and who therefore discredit the theory of "nerve anastomosis." From my own observations, I can have no doubt that in many cases of neurotomy a *complete anæsthesia* is certainly present, and that there are all grades of gradually increasing sensation, till we reach a point at which it becomes exceedingly difficult to say for certain that the tactile sense is not due to a regeneration of the divided nerve. The extent to which this supplementary sensation is developed varies according to the nerve divided, and even then is by no means constant.

There are now recorded a sufficient number of cases to render it certain that very acute sensibility *may* be retained after section of nerves supplying definite skin areas, and I will only mention that on the Continent unequivocal instances, verified in some by post-mortem examination, have been detailed by Richet, Leudet and Delabost, Baudens and Israel. Two other cases quite as interesting have been recorded in England by Savory and Butlin, and these I will venture to quote in greater detail.

In THE LANCET of August 1st, 1868, Mr. Savory describes a case of neuroma in which he excised a considerable portion of the musculo-spiral nerve with the tumour. The following is his description of the state of the parts after the operation: "From the time of the operation the muscles of the back of the forearm were paralysed, and the hand dropped forward from the wrist. But when testing the sensibility of that portion of the skin of the hand which is supplied by branches of the radial nerve, we were not a little astonished to find that it was but slightly impaired. When the skin upon the outer part of the back of the hand or over the back of the thumb and forefinger was slightly

Digitized by Google

pricked, the man cried out sharply. He could distinguish in the same region two points of contact, when they were not less than an inch apart, both in the long and tranverse axis of the hand. When they were closer than this, on any part of the back of either hand or forearm, he confused them, and, indeed, in comparing the sensibility of this region with that of the inner portion of the back of the hand and two inner fingers, or with the corresponding part of the opposite hand, no very striking difference could be detected. All portions too, of the back and sides of the middle finger appeared equally sensitive. He could distinguish also between the contact of hot and cold bodies in this region as well as in other parts. He always remarked the distinction between the touch of a cold steel sound and one that had been previously dipped in hot water. When desired to experiment on himself by touching, scratching, or pricking the different parts, he repeatedly declared either that he could perceive no difference of sensibility or that the radial portion of the dorsum of the hand was rather more sensitive than the other half. These observations were carefully repeated in various ways day after day, with a uniform result; indeed, the man at last got tired of them, concluding, no doubt, that the existence of acute sensibility had been abundantly proved. It need hardly be said that in many of these experiments the man was blindfolded and otherwise prevented from forming any idea of what we did except through the sense of touch. Now, what is the interpretation of this remarkable fact? All anatomists will agree that, so far as ordinary dissection goes, the skin on the outer half or thereabouts of the back of the hand, and of the back of the thumb, forefinger, and outer portion of the back of the middle finger, is supplied only by branches of the radial nerve; and when any variation is witnessed in the distribution of this nerve to the back of the hand, it is almost always that it supplies more than the usual portion of integument, going on sometimes to the ring finger. I cannot doubt, therefore, that in this instance the parts in question were supplied in the usual way, only through the branches of the radial nerve. But then how could these parts retain sensibility after the removal of some inches of the nerve trunk? I can only account for it thus: We know that in the forearm just above the wrist some small branches of the external cutaneous nerve communicate with the radial, and it may be that at this junction the radial receives filaments from the external cutaneous which so pass down to be distributed with the filaments of the radial even to the skin of the hand. This seems to me the most probable view of the matter—indeed the only reasonable one."

The next case was reported by Mr. Butlin in vol. xxv. of the Pathological Society's Transactions:—"D. D——, aged thirty-two, was admitted into St. Bartholomew's Hospital with a broken back, in June, 1873, of which he died three or four days after admission. There was noticed on his left arm, three or four inches above the wrist, a long oblique scar, apparently the remains of a tolerably deep and severe wound; the ring and little fingers were exceedingly contracted, the little finger especially drawn in towards the palm. Neither of them could be at all straightened; the skin covering them was tense and glazed. The muscles of the ball of the little finger were atrophied to an extreme degree, and contracted. The interossei and abductor indicis, the abductor pollicis, and the inner head of the flexor brevis pollicis were in the same condition. But, so far as could be ascertained by careful examination, there was no loss of sensation, feeling being as complete in one hand as in the other. The history which he gave of this (for he was in complete possession of his faculties until shortly before his death) was as follows:—Fourteen years previously his forearm was wounded, and he was in the hospital for fourteen weeks. At the time of admission, and for some time afterwards, the hand was 'numb' on the inside. He regained feeling in it before he went out; his fingers became drawn down afterwards. A post-mortem examination showed that the ulnar nerve had been completely divided about three inches and a half above the wrist; the upper portion was firmly united to the anterior surface of the tendon of the flexor carpi ulnaris; the lower portion was united to the same tendon, but to its posterior and external aspect. No communication whatsoever could be discovered between the extremities of the divided nerve, which were not only far apart, but also on a totally different plane. The upper portion showed very little atrophy, even when examined with the microscope. About three-fourths of an inch above its point of union with the tendon was a large bulbous swelling, similar to the swelling found at or about the ends of nerves in stumps. The lower portion of the nerve was exceedingly atrophied. Sections examined microscopically showed that it was composed almost wholly of connective tissue, but here and there could be seen small points which had deeply coloured with carmine, and which resembled axis cylinders."

The manifest care expended on a thorough investigation of the recorded cases, and the high reputation of many of the surgeons under whom the patients happened to be placed, leave little or no room for doubting the reality of the retention of a certain amount of sensation in the area supplied by the divided nerve. The more care, then, is necessary in arriving at the conclusion that in the case of any injury regeneration and reunion of the divided ends have occurred; for if the surgeon disregard the possibility of a supplementary nerve supply, he is apt to refer any signs of returning sensation to a reunion of the nerve, and not to its true cause. In addition, then, to testing the tactile power and amount of anæsthesia, it is necessary to note the presence or absence of paralysis and of trophic changes. If coincidentally with a gradually returning sense of touch the nutrition of the part improves, if previous trophic lesions pass away, and if—what is most important—the atrophied muscles resume their normal bulk, their reaction to faradaism, and their contractile power, it may fairly be considered proved that a reunion of the divided nerve has occurred. But in the absence of these additional symptoms of regeneration, *a simple return of sensation does not afford sufficient proof of new nerve formation.*

With regard to the extent to which this supplementary sensation (*sensation supplée* of Létiévant) may be present, Létiévant writes: "These supplementary sensations are very imperfect; but, in proportion to the length of time which has elapsed since the section, they undergo by use a greater development. They are modified by certain local pathological conditions. Thus, after certain nerve divisions practised chiefly for neuralgia, there is produced a sort of local stupor which masks the supplementary sensibility for a few days. Sensibility is restored as this stupor is dissipated." With these remarks, my own experience would lead me to agree, and I would only add that in other cases the supplementary sensation appears to be most marked immediately after the nerve section, and that it subsequently disappears. The manner in which this supplementary sensibility is kept up is thus stated by Richet: "As both the loops and filaments which end in the touch corpuscles are compound, containing fibres from the median, radial, and ulnar nerves, section of one of these trunks is powerless to deprive of sensibility the corpuscles, which are the essential organs of touch." This is *à propos* of a division of the median. Arloing and Tripier in the *Annales de Méd. Vét.*, 1876, express much the same opinion, and state that after division of three out of the four collateral nerves on the toe of a dog, sensibility still remains, but is destroyed by dividing the other nerve. This, however, is certainly not applicable in its entirety to the human subject, as there can be no doubt that in many cases—e. g., after division of the median at the wrist—the fingers are in parts frequently entirely anæsthetic. Israel in the case quoted by him is inclined to ascribe the cause of the supplementary sensation to a chance union of the proximal ends of the injured nerves with another nerve which was yet intact; this condition, however, is not essential for the presence of supplementary sensation. Mr. Savory, with more probability, refers this condition to what I may call the "coarse anastomoses" in contradistinction to Richet's explanation; and in the case of injury to the musculo-spiral, on which he bases his arguments, instances the union of small branches of the external cutaneous with filaments of the radial nerves. No difficulty need be found in accepting either Richet's or Savory's explanation. It has been proved that the nerves can transmit currents equally well in either direction; and considering the comparatively small bonds of union which exist, and the fact that they do not enlarge as do the collateral vessels after ligature of an artery, the imperfections of the supplementary sensations will not excite surprise.

In addition to simple inability to perceive the contact of various bodies with the skin, there is often found a want of power to localise correctly the exact spot touched. Frequently a patient will perceive that some part of the hand is being touched, but on being asked to name the finger or spot of contact he makes mistakes. Thus, on pricking the back of the finger he fancies that it is the front which is

Digitized by Google

being experimented on, or else another finger, or even the palm or back of the hand. There seems to me to be no particular law as to this transference of sensations; sometimes the patient fixes on a spot which is really devoid of sensation, at other times on a sound digit.

The sense of pain as evinced by pricking or pinching is generally lost in proportion to the amount of anæsthesia, but in a considerable number of cases all sense of pain is absent, and yet there is not complete anæsthesia. The reverse is rarely the case. In my opinion this is due to the fact that a more intense impression is necessary to give rise to pain, and that a proportionately perfect nerve supply is requisite, while the sensation of touch can be more or less clearly perceived even when the nerve paths are more or less damaged. In rare cases the skin may be in a hyperæsthetic condition; this I think only occurs in cases of incomplete section, in conjunction with neuritis as a rule, but sometimes apart from this in the *neighbourhood* of trophic lesions.

The *muscles* supplied by the divided nerve are paralysed by its section, and the subsequent changes that take place in them have been already described. It remains, however, to notice the deformities which result from their atrophy. The exact method by which the altered condition of a muscle after nerve section causes contractions and deformities appears to be very imperfectly understood. It is generally spoken of as if it were an active contraction either of the muscle itself or else of the degenerated tissue which takes its place. I believe that this view is not correct, and shall endeavour to prove my assertion. The muscle undergoes atrophy; it shrinks and grows smaller in every diameter, but not with any degree of force sufficient to cause actual deformity. No; the whole secret of the process lies in the fact that *the muscle shrinks only so long as it is unapposed*. If, therefore, its origin and insertion be unduly approximated *during the process of atrophy*, they will remain in such a condition when the atrophic changes have ceased, not because they have been drawn together by such changes, but that the atrophy found them in a certain position and fixed them there. For instance, after section of the median nerve in the upper arm it is very common for permanent flexion of the digits to ensue, but the reverse is not the case after the division of the musculo-spiral; the fingers and wrist are not then extended, but, on the contary, are flexed. Whence the difference? I think it is easily explicable. When the hand is paralysed, or when it is simply not in use, the fingers naturally lie in a position of flexion, and in this position they are gradually fixed by the atrophic changes. There is evidently no active contraction, for if it occurred in the flexors in the case of division of the median, the same result ought to follow in the extensors on section of the musculo-spiral, and hyper-extension of the fingers and wrists would result. This condition is prevented, however, by the naturally bent position of the hand, and by the frequent exercise of the flexors. Similarly, after infantile paralysis the most common deformities are equinus and bent knee. But in many cases the whole of the muscles of the lower extremity are equally paralysed. Why, then, are not the leg and foot sometimes extended? Simply for the very good reason that both of them, either in sitting or walking, but more especially the former, naturally fall into the position in which they are subsequently fixed by the shrinking of the muscles, which occurs at a period when from the nature of the illness the patient is kept from active exercise.

I am, then, very strongly of the opinion that the "irresistible power of contraction of the paralysed muscles" described by some authors has no existence in fact, but am quite willing to allow that when shrinking has once occurred the muscles cannot be artificially restored to their normal length. There is, however, one form of active contraction which is sometimes very troublesome—namely, that which is due to the unbalanced action of the unaffected muscles; it may produce a real deformity, though not, I think, very frequently.

The changes in the electric irritability of divided nerves appear to commence very early after section. MM. Cossy and Dejeune found that after section of the sciatic in guinea-pigs, the excitability of the peripheric segment is diminished on the second day, and after the third is entirely lost. Leegard (in the *Archiv für klin. Med.*, 1880), says that at first the irritability of the divided nerve—i.e., of its distal end—is slightly increased in some cases, but not constantly; and he agrees with the above observation, that by the third day it no longer reacts to electricity.

The electrical condition of the muscles has been already referred to in speaking of trophic changes, and the extent to which a muscle will respond to electrical stimuli after nerve lesions has been made by some authors a point of great importance in the prognosis of such injuries. It must not, however, be thought that the absence of all reaction to the proper stimuli in any way indicates that motion is permanently lost, for, as we shall see presently, if the continuity of the nerve be re-established, regenerative changes will take place in the muscle, at any rate for a considerable time after the date of the original lesion. But although the failure of a muscle to react to electrical stimuli is not by any means to be considered an indication that it is beyond recovery, the behaviour of the muscle to the electric current nevertheless affords the most valuable evidence as to its connexions with its trophic nerve centre. On examining a muscle in a natural condition with a galvanic current, it will be found that the kathodic closure contraction (K.C.C.) is greater than the anodic closure contraction (A.C.C.), a condition which is briefly expressed by the formula K.C.C. > A.C.C.

It has been shown by Erb[1] that in a muscle separated from its motor nerve this reaction undergoes a marked change, the A.C.C. becoming first equal to and then greater than the K.C.C., a reaction which, together with other electrical conditions, goes to make up the so-called "reaction of degeneration." This alteration in the electrical irritability of the muscle is well and briefly put by M. Nicaise.[2] He says: "During the first fifteen days the faradisation curve becomes gradually depressed. After the third week, the muscle is no longer excitable, at least through the skin. Towards the sixth week, in favourable cases, the excitability reappears, and gradually increases until it reaches the normal reaction. But the galvanisation curve follows an entirely different course. During the first fifteen days it follows the faradisation curve; but from the third week, when the interrupted currents have no longer any effect, the galvanic reaction is exaggerated, the curve is raised, soon exceeding the normal, and reaches its maximum when the other is at its minimum. At the moment that repair begins to take place the phenomena follow an inverse order; and at the same time that the faradic curve is raised the galvanic curve is lowered, and both gradually return to the normal level. If, instead of a favourable case, we suppose a case in which the regeneration of the nerve does not occur, there is no ascent of the faradic curve, and the galvanic curve, after being elevated, falls again to the normal, and then continues to sink until the reaction becomes *nil*."

The above paragraphs form a very accurate summary of the conclusions arrived at by Erb and other experimenters. The care with which the results have been recorded leave no doubt in my mind as to the accuracy of the observations, and it only remains to notice, before proceeding further, that these conclusions are the result of experiments on animals, and not of clinical observations on man. These experiments I have not myself repeated, both on account of the difficulty encountered in carrying them out in this country, and also because I have no doubt that the conclusions arrived at are correct. Moreover, inasmuch as I am interested more particularly in the nerve injuries of man, I have found that I could better occupy my time by examining the electrical reaction in the muscles after nerve injuries such as are met with clinically. And here I would point out again that the changes that occur in the nerves or in the parts supplied by them, as noted by experiments on animals, do not necessarily find their exact counterpart in similar conditions in man. This is a point that is duly appreciated by Nicaise, who says, after concluding the paragraph I have quoted, "Do the same phenomena occur in man as in animals which are made the subject of experiment? Precise observations are not sufficiently numerous to permit this fact to be definitely affirmed. A minute study of these electric phenomena in the traumatisms of nerves is, then, necessary before we can apply in all certainty to man the results observed in animals."

With this I entirely agree, but have so far searched in vain amongst the now numerous recorded cases of nerve injury for any information on this point. My own observations, however, lead me to disagree with Erb, in some particulars at least, and I would take the present opportunity of acknowledging the valuable assistance I have received in the examination of patients from Dr. Steavenson, electrician

[1] Handbook of Electro-Therapeutics.
[2] Article in Ashurst's Encyclopædia of Surgery, vol. iii.

Digitized by Google

to St. Bartholomew's Hospital. I have found that in cases of nerve section in man the faradic excitability of the paralysed muscles has disappeared with much greater rapidity than in animals, for, whereas Erb states that it gradually fades and finally disappears in the third week, I have found absolutely no reaction to the strongest currents as early as the third or fourth day. In one case only excitability persisted until the eighth day.

With regard to the galvanic current, there is, again, a marked difference between the conditions in men and animals. In the latter the galvanic irritability of the muscles is said to become greatly increased at the second week, and in the third week the excitability is so great that contractions are excited by the current evolved from only two or three cells. Such is not my experience. I have never seen but once, and then it was doubtful, the least increased excitability. On the contrary, I have found that the galvanic irritability diminished rapidly, so that in two or three weeks, at a time when theoretically excitability should be at its height, strong currents produced but slight fibrillar contractions, which were also very slow and wavy. And, whereas by experiment the date of the final disappearance of galvanic excitability has been fixed at about eight or ten weeks, I have found it to vary in man from about the third to the sixth week.

With respect to the alterations in reaction to the kathodal or anodal closure currents, my own observations are in accordance with those of others. In about a week or ten days I have found that the anodal closure contraction was either equal to or greater than the kathodal closure contraction. This reaction is of great value from a diagnostic point of view, and is also most reliable. Considerable care is nevertheless requisite in investigating the affected muscles.

The next point for consideration is the permanency or otherwise of these altered reactions. Supposing that at the end of a few weeks all electrical excitability has disappeared in the paralysed muscles, when must we look for its recurrence, and in what way does its absence influence the prognosis? To this it may be answered that, if the divided nerve does not reunite, the electrical irritability will not return; but that, if it does reunite, *voluntary power will return before electrical excitability*. The first sign of repair as regards the muscles must not, then, be looked for in the electrical reactions, but in the return of function; and the continued absence of electrical irritability is not to be looked upon as sufficient ground for a bad prognosis. Voluntary power often returns many months or even a year or more before electrical excitability—a fact which is difficult to explain, but of which I cannot have the slightest doubt.

Does faradic or galvanic excitability return first? I cannot answer this question quite so definitely as some of the others. In some cases both have returned at the same time; in others the muscles have contracted to the faradic current whilst yielding no response to galvanism. I have never seen galvanic irritability return before faradic. In most of the cases I have observed, the galvanic reactions, when they first reappeared, were normal in quality; but in one case, where they did not return until six months later than the faradic reaction, the reaction of degeneration was well marked. The following notes of cases illustrate most of these points.

CASE 1.—James D——, aged thirty-four, divided his ulnar nerve on April 7th. 9th: No reaction to faradism of ulnar muscles; good reaction to galvanism of ditto. 14th: No reaction to faradism; very slight reaction to galvanism.

CASE 2.—Geo. H——, aged thirty, divided his ulnar nerve on May 8th. 11th: Muscles supplied by ulnar nerve react to faradism; galvanic current, A.C.C. = K.C.C. 13th: Complete loss of faradic contractility in all muscles supported by the ulnar nerve; very slight reaction to galvanism.

CASE 3.—Emile M——, aged forty-seven, divided his ulnar nerve at the elbow on Feb. 22nd, 1884. 25th: Faradic current; no reaction of muscles supplied by ulnar nerve.

CASE 4.—John S——, aged thirty, divided his ulnar nerve at the wrist on Feb. 23rd, 1885. 24th: Faradic current; all muscles react. Galvanic current, K.C.C. > A.C.C.; no increased irritability; ulnar muscles paralysed. 26th: Faradic current; slight reaction of interossei. Galvanic current, A.C.C. = K.C.C.; no increased irritability. 27th: No change. 28th: Faradic current; marked diminution of excitability. Galvanic current in third interosseous muscle, A.C.C. > K.C.C.; other interossei as before. March 1st: Faradic current, only the faintest contraction. Galvanic c[illegible] A.C.C. > K.C.C. 4th: No reactions to faradism. The faintest tremor to galvanism.

CASE 5.—Henry B——, aged forty-seven, divided his ulnar nerve on Feb. 6th. 20th: Complete loss of both faradic and galvanic contractility.

CASE 6.—Annie B——, aged twenty-seven, divided her median nerve at the wrist on September 27th, 1885. On account of her hand being entirely covered with antiseptic dressings I was unable to examine the condition of the muscles until the third week. On October 20th there was found to be no reaction to faradism in either the opponens or abductor pollicis. The same muscles gave the reaction of degeneration to the galvanic current (A.C.C.>K.C.C.), but instead of there being marked excitability there was great loss of galvanic irritability, and the contractions were slow and wavy. Oct. 30th: The muscles supplied by the median nerve require eighteen more cells to cause a contraction than do those of the other hand, and then scarcely react.

It will thus be seen that after nerve section the paralysed muscles usually fail to contract to the faradic current after the third or fourth day. That at the same time, tested by the galvanic current, A.C.C. = K.C.C., and later on A.C.C.>K.C.C. In from three to six weeks there is complete loss of all electric excitability.

In support of my statement that voluntary power returns before electric excitability I append the following extracts from cases I have observed:—

CASE 1.—J. C——, aged seventeen, divided his musculo-spiral nerve on March 25th, 1883. On April 28th the operation of secondary suture was performed. On July 27th there was some return of power in the previously paralysed extensor muscles, but no return of electric excitability. On Nov. 16th there was almost perfect restoration of power, but no reaction to galvanism or faradism. On March 25th, 1884, one year after the injury, there was complete restoration of voluntary power, but still no electric excitability. Oct. 9th, 1884: Wrist extensors and extensor ossis metacarpi pollicis react to faradism and galvanism, but the extensors of the phalanges of the fingers and thumb do not react.

CASE 2.—T. M——, aged twenty-four, divided his median nerve on July 20th, 1882. On May 5th, 1883, the divided ends were sutured. Nov. 26th, 1883: Return of power in opponens and abductor pollicis. No reaction to galvanism or faradism. March 28th, 1884: Muscles quite as good as on other hand; very slight reaction to a strong faradic current. Sept. 22nd, 1885: Reactions normal to faradism and galvanism.

CASE 3.—W. W——, aged nineteen, divided his ulnar nerve at the wrist. Seven months later the divided ends were sutured. In five months there was a return of voluntary power in the interossei and muscles of the ball of the little finger. A year later this hand was quite well, but there was yet no reaction to electrical stimuli.

CASE 4.—C. R——, aged eleven, divided her ulnar nerve in the forearm. Three months later secondary suture was performed. Muscular power began to return in about eighteen months. Six months later the muscles supported by the ulnar nerve reacted to faradism, but not to galvanism. After an interval of another six months galvanic irritability was restored, but the reaction of degeneration was well marked.

RESECTION OF AN IRREDUCIBLE AND GANGRENOUS INTUSSUSCEPTION.

WITH A CONSIDERATION OF THE TWO CHIEF METHODS OF TREATMENT: INFLATION AND ABDOMINAL SECTION.[1]

BY LAWFORD KNAGGS, M.A., B.C. CANTAB., F.R.C.S. Eng.

THE patient, aged five years and a half, a strong healthy boy, had been suffering from a cold for a week. His appetite had been small, and the bowels had not acted satisfactorily, a scanty evening motion taking the place of the usual morning one. On November 9th he came down to breakfast, looking pale and complaining of stomach-ache. A domestic aperient was administered, and after breakfast he vomited; but the bowels being moved only twice, and very inefficiently, a second aperient was given, and immediately vomited. The pain continued, and was

[1] Read before the Leeds and West Riding Medico-Chirurgical Society, February 4th, 1887.

Digitized by Google

subsequently described as of a spasmodic character, but not very severe. The vomiting became frequent, and any attempts to take food caused retching. I saw him in the evening. The vomited matter was white and frothy. In the right iliac fossa could be felt what seemed to be thickened and solid coils of intestine, unlike anything elsewhere. The spot was tender, and to it he referred his pain. As I was manipulating these coils something seemed to move under my fingers, and I was unable afterwards to distinguish what I had previously felt. The manipulation gave pain, and caused retching. Temperature 98°; pulse 90. I concluded that what I had felt was probably an intussusception which had resolved under manipulation, and I ordered four minims of tincture of opium in one drachm of water every four hours; no food to be taken by the mouth. I saw him again later, and, the vomiting and pain continuing, I substituted subcutaneous injections of morphia with atropine for the opium. The tumour had not reappeared.

Nov. 10th.—Vomiting stopped after the subcutaneous injections, and he had slept fairly during the night. There was now a lump on the right side below the umbilicus, dull on percussion, somewhat pear-shaped, with the stalk sloped towards the right flank. It could not be indented by pressure; it was tender. There was no action of the bowels, but flatus had been passed. The rectum was empty. A very small quantity of urine had been voided. Tongue moist. Temperature 98°; pulse 100-110, good. The dose of morphia and atropine was increased, and he was kept well under its influence throughout the day, being allowed beef-tea by the mouth, but fed regularly by the bowel. In the evening he vomited some brown-looking fluid not unlike beef-tea—not offensive. The lump remained unaltered, and showed through the rectus as a prominence.

11th.—Passed a good night; pulse 120; tongue moist; no vomiting. Tumour less distinct, but perceptible and dull. The A.C.E. mixture was administered, and the bowel inflated with Lund's insufflator. Air could be felt under the fingers placed upon the tumour; this disappeared gradually, and the abdomen became generally distended and resonant, but there was no feeling suggestive of resolution having taken place. In the afternoon Mr. Teale and my father saw the case with me. All doubt as to the nature of the tumour had been set at rest by the passage of a pint of fetid dark-brown liquid fæces, having a reddish tinge due to blood. It was thought to come from above the obstruction, and, in the absence of any distinct tumour, to indicate that probably partial or complete reduction had resulted from the inflation. The operation therefore was to be repeated in the morning. The child passed an easier night under the morphia and atropine, but woke every half hour, complaining of "that awful pain." Two motions of the same dark fetid character, but now containing mucus as well as blood, were passed.

12th.—He is evidently worse. Pulse 140, compressible; tongue dry, slightly brown, and covered with sordes; features pinched. Inflation was repeated, but with no more satisfaction. With a view to operation, he was now fed by the mouth; so that with nutrient enemata, each containing one drachm of brandy, every three hours, and champagne, brandy-and-water, calves' foot jelly, chicken broth, and essence of beef by the mouth, he had taken a considerable amount of nourishment and stimulants before he was again seen by Mr. Teale at 7.30 P.M. His condition then was much improved, but his pulse was 146, his temperature 99·4°, his tongue dry, and he was incoherent and rambling. He had passed another liquid motion containing more blood and mucus than the previous ones, and much more offensive.

It was now thought that the risks were greater if no interference was attempted, and so it was decided to operate, and if it became necessary to remove the intussusception to attach the open ends to the abdominal incision in order to economise time, and so tend to lessen the shock. With Mr. Teale's assistance, my father giving the anæsthetic—A.C.E., for which ether was eventually substituted,—I opened the abdomen by a median incision three inches long, and at once found the tumour lying rather deeply on the right side. There was considerable difficulty in getting it to the surface without undue traction, and when this was accomplished nothing could be made out until the whole mass was drawn outside the abdomen. It was nearly a foot in length and curved, and proved to be an intussusception into the small intestine, in which it was very tightly strangled, the outer layer being arranged around the upper part in collar-like rolls. The intussusception passed through the ileo-cæcal valve, and for three or four inches into the large intestine. It was quite loose here, and for two or three inches in the adjoining part of the ileum, and it could be easily pushed back at this part, but the mass was so tightly gripped above, that prolonged and steady traction, both at the upper and lower ends of the tumour, had not the least effect upon it. Moreover, there were several dark-coloured patches upon the outer layer, where the pressure was greatest, suggestive either of gangrene or blood beneath. The attempt to reduce the invagination was abandoned, and the intestines protected by lint wrung out in carbolic lotion. Following a suggestion of Mr. Teale's, with the object of saving as much bowel as possible and avoiding a subsequent union of small with large intestine, I made a transverse opening in the ileum three inches above the valve, and through this pulled out the lower part of the invagination. A ligature was applied to it high up and the free end removed; it was black and offensive. I then found that there was a small perforation about an inch below this incision through which blood and mucus could be squeezed from inside, so I made the section of the gut an inch nearer the colon than I had intended. Before doing this I clamped the bowel above and below the invagination with Treves' clamp, and ligatured the mesentery to the tumour half an inch from the bowel with five or six ligatures. The tumour was then removed between the clamps and its attached mesentery cut through. At this stage the patient's state became very serious, and it was deemed advisable to conclude matters as quickly as possible. The upper end was attached to the abdominal incision by deep sutures passed through the abdominal wall, and the peritoneal and muscular coats of the bowel, and by superficial ones between the skin and the mucous membrane. To do this the clamp had to be removed, and the open end was held by a pair of Knowsley Thornton's pressure forceps, an instrument that proved extremely useful, completely closing the gut and allowing it to be manipulated quite out of the way of my fingers. On removing it to put in the superficial sutures, a small piece of sponge effectually prevented any escape of fæces. The lower end was then fixed, the incision closed, a dressing applied, and the child put back to bed. He was then pulseless, but soon came round from the ether, and after stimulant had been administered by the bowel and under the skin, a small pulse could be felt. He was very restless, never rallied, and died about an hour and a half after the operation.

The success that has attended inflation in cases of intussusception has been so satisfactory that it is not surprising it has now become recognised as the first operative procedure which should be attempted. The ease with which it can be carried out, the simplicity of the means for its performance which can be so readily extemporised, are likely to render it a very popular method with practitioners, who may be so situated as to be beyond reach of the ordinary hospital requisites needed for serious operations. A clear appreciation of the dangers to which any operation is subject by no means makes it less useful, but rather enhances its value by ensuring a more thoughtful intelligence in its performance. I feel therefore tempted to try to bring out clearly the dangers to which forcible distension of the bowel by air or water is liable; the more so because of the usual text-books Fagge's "Medicine" is the only one in which I have found special reference to them, and I believe that there exists a very general opinion that if inflation does no good, at least it can do no harm. The following eight cases show that there are two great dangers in the operation: injury to the bowel, even to the point of rupture, and shock:—

CASE 1. (Mr. Bryant.)—Boy, aged six months. During inflation the abdomen became generally distended; no air escaped per rectum. The child became almost pulseless. Post-mortem: Fæcal extravasation. "The left half of the transverse colon and splenic flexure were constricted and perforated." A second opening was found lower down in the sigmoid flexure. (Harveian Lectures, 1884. This is probably the same case as that alluded to by Dr. Fagge and Mr. Howse in the Med. Chir. Trans., vol. lix.)

CASE 2. (Mr. Symonds.)—Boy, aged five months. During inflation the abdomen became suddenly distended, and when opened brownish mucus was found inside the peritoneal cavity. Perforation had occurred in a portion of the invaginated bowel, which was easily reduced. (Not published.)

CASE 3. (Mr. John Thomas.)—Boy, aged five months. The tumour could be felt per rectum. About nine ounces of water were injected, when a rumbling noise was heard in the abdomen. No air returned. Post-mortem: In the pelvis

Digitized by Google

was half a tumblerful of water. (THE LANCET, Dec. 25th, 1886.)

CASE 4. (Dr. Tyson.)—Case where oil was found in the abdominal cavity after death. (*Brit. Med. Jour.*, Dec. 3rd, 1881.)

CASE 5. (Dr. Moxon.)—Child, aged seven months. After inflation and enemata the colon had partially given way in several places. (Med.-Chir. Trans., vol. lix. Probably the same case is recorded by Mr. Bryant in the Harveian Lectures.)

CASE 6. (Mr. Bryant.)—Boy, aged seven months. The bowel between the intussuscepted portion and the sigmoid flexure was partially ruptured in many places. The peritoneal covering was cracked and turned out, and in the sacculi the longitudinal muscular fibres were torn and the transverse separated. (Harveian Lectures.)

CASE 7. (Mr. Bryant.)—Child, aged seven months. The bowel was inflated, and the child became collapsed, convulsed, and died. (Harveian Lectures.)

CASE 8.—Dr. Fagge and Mr. Howse mention a case of an adult in which a large injection of seven pints injudiciously administered was supposed to have caused the death of the patient. (Med. Chir. Trans., 1876, vol. lix.)

In one only of these cases was the age not stated, but of the remaining seven it is interesting to note that in all three cases in which rupture occurred the age of the patient was only a few months; that the two in which the bowel was seriously injured were only a month or so older; and that six of the seven in which harm resulted were children less than eight months old. Admitting the greater frequency of invagination in young children, these figures point strongly to the conclusion that the intestines of infants are not well suited to bear great distension. Nor is this astonishing when we bear in mind their thinness and delicacy.

What bearing have these facts upon the question of the administration of an anæsthetic during inflation? In adults anæsthesia is dispensed with, that the operator may obtain information from the sensations of his patient and regulate the continuance of the operation by them; but in infants insensibility is usually deemed advisable to ensure the proper application of the method, and by the abolition of spasm to improve the chances of its success. Admitting that a surgeon is not likely to obtain much information from the intelligent co-operation of a conscious child forcibly subjected to inflation, yet if it is anæsthetised there is the very obvious danger that the distension may be carried to too great an extent in consequence of the inability of the patient to feel or to express any discomfort. Now it has been pointed out that to employ inflation when sloughing of the invaginated gut is in progress is sure to result in disaster; but in considering the applicability of this method to any particular case, it is necessary to bear in mind that the only certain sign of sloughing is the passage of portions of gangrenous gut, that acute symptoms do not mean the onset of gangrene, but probably the commencement of conditions which will end in gangrene if the patient survive long enough, and that in cases in which gangrene has been supposed to exist the facts have as often as not been found to belie the supposition. The operation, then, is only contra-indicated in those cases in which there is certain evidence of sloughing in the passage of portions of gangrenous intestine. Sometimes, quite distinct from gangrene of the invaginated intestine, there are other conditions of the tumour, or having some connexion with it, which predispose the patient to suffer injury from forcible distension of the bowel. Such conditions are gangrene, ulceration, and perforation of the outer layer from outward pressure of the tumour, or ulceration of a neighbouring part of the bowel, a not very uncommon accompaniment of intussusception, and which is sometimes thought to be the exciting cause, and at others may be produced by the invagination. The following instances will illustrate these conditions:—

CASE 9. (Dr. Charlewood Turner's case.)—There was found ulceration of the cæcum, into which the apex of the tumour had passed. (Path. Soc. Trans., 1881.)

CASE 10. (Mr. Henry Morris's case.)—On the sixth day the outer layer of an intussusception of the small intestine was found gangrenous from pressure, and almost perforated in three or four places. (Path. Soc. Trans., 1877.)

CASE 11. (The case reported above.)—On the fourth day a minute perforation existed in the outer layer at a place where the tumour was easily reducible, and several places very suggestive of commencing gangrene where the invagination was tightly grasped.

Though perforation in Dr. Turner's case did not take place till three days after the employment of large injections had been discontinued, yet their existence must have rendered forcible distension a very hazardous proceeding, and I feel that it was a piece of good fortune that no harm resulted in my own case.

(To be concluded.)

ON THE

CHEST DISEASES AFFECTING WORKMEN AT COPPER WORKS.[1]

BY H. A. LATIMER, M.R.C.S., L.S.A.,

SURGEON TO THE SWANSEA HOSPITAL, THE MORFA AND PORT TENNANT COPPER WORKS, &C.; PRESIDENT OF THE SWANSEA MEDICAL SOCIETY.

I HOPE I shall meet with approval in bringing before the notice of the profession a diseased condition with which many practitioners are brought into occasional contact, and which forms a large part of the practice of others who, like myself, are engaged in attendance on persons who labour in one of the special industries of this country. I allude to the chest complaints set up in those who are employed in the manufacture of copper and yellow metal—staple industries of the town of Swansea and its neighbourhood. I am compelled to adopt a somewhat indefinite nomenclature for the title of my paper, because, by the very nature of the pathological changes induced in the chest primarily, and in the general system secondarily, I am prevented from giving a definite title to the matter under consideration. Thus, for instance, I should be failing in my purpose were I to speak of chronic bronchitis, or of chronic interstitial pneumonia, and so on, when dealing with the matter at issue; for either of these diseases, alone or together, form only links in the chain of morbid conditions which are set up by the pulmonary irritations caused by the oft-repeated inhalations of noxious substances, whether gaseous or mechanical, which act as the irritants and disease-producers amongst the workmen who labour under such exposures. Indeed, for many years past, I have been in the habit of alluding to the cases which form the subject matter of this paper as examples of "copperman's chest," a title which perhaps fails to convey to the uninitiated any sense of pathological entity, but which is sufficiently comprehensive to carry with it to the minds of students a knowledge of what condition the sufferer is in. I venture to say that no practitioner who has the care of workmen engaged in the manufacture of copper will disagree with me in thus denominating a class of disease with which he is brought into familiar contact.

What, then, may one expect to find in the "copperman's chest"? Two things will always be found, at least; and these two things are bronchial disease and interstitial pulmonary change, both more or less pronounced in character. As time progresses other organs than the lungs become affected, and the sufferer presents a very storehouse of symptoms for the consideration of his medical attendant. I think I shall best deal with the matter by a description of a patient of mine who is now under my treatment, as his case is a very typical one and well adapted for my purpose.

S. T——is now fifty-six years of age, and has been engaged in copper works since eight years old. He has always been a very steady and abstemious man. He started as a labourer's help, became a labourer engaged in discharging coal and ore, moved on to be a furnace-man, then worked in the refinery, and finally became what is known as a "gaffer" or foreman. His family history has a well-marked phthisical taint in it. At different periods he contracted colds like other people, and the colds always affected the chest; but there was nothing notable about this circumstance until the last ten years or so, since which time he has been more or less a sufferer from cough and shortness of breath. During this period his colds would take the course to which I am now well accustomed in men of his class—viz., they would be characterised by chronicity of process and by resistance to ordinary remedies for that class of disease. For some years past he has never been free from some shortness of breath and cough. For the past twelve months he has been quite unable to work, as he has suffered from

[1] A paper read at the Swansea Medical Society on October 29th, 1886.

Digitized by Google

increasing shortness of breath with dyspnœa on exertion, from asthmatic attacks, from drenching perspirations by day and by night, from great disinclination for food and inability to digest the same, and from constantly increasing weakness as a result of those troubles. The heart beats feebly and frequently in its efforts to pump the blood through the lungs, and, under the presence of constantly increasing resistance there, has become overloaded, so that its right side has failed to empty itself, and there is venous regurgitation. The stomach and other abdominal viscera, being overloaded with retarded blood, and so passively congested, are affected with catarrh, and the kidneys are with difficulty excreting a scanty urine, which is loaded with albumen. S. T——'s case is on all fours with many others that I have witnessed, and, in reply to my frequent advice that he should shift his quarters and his employment at an early period in treatment, I have been told, "What can I do, sir? I am too old now to start afresh, and my state of health is not such as to commend me to any other employers of labour than those for whom I have worked for many years past." And so it happens that the sufferer drifts into the condition of confirmed and fatal disease.

I have said that all the cases present at least two conditions—viz., those of bronchitis and chronic interstitial pulmonary changes. There is a wide variance, however, in the type of the former complaint. With many persons the bronchitis remains to the end the main morbid condition, and loud rhonchi—sonorous or mucous in character—indicate the chief foci of disease. This bronchitis becomes chronic, and, emphysematous changes occurring in the lungs, the tubes yield here and there, and form large bronchiectatic cavities, from which great quantities of offensive sputum are discharged at different times. The condition is one which is prone to mislead inattentive observers, who are apt to regard the bronchiectatic cavities with their surrounding layers of condensed lung tissue as being vomicæ caused by the ravages of tubercular phthisis. But the extensive character of the morbid condition, as well as the duration of the disease, and the concomitant conditions of emphysema and cardiac trouble, are sufficient to negative such a view of the case, even if we exclude the information given us by careful physical examination of the patient. One such patient as I have now been describing died under my care last year. For many years past he had been confined to the house in the winter months suffering from dyspnœa, gastric catarrh, and all the bronchial disease just spoken of. With the first cold winds of the year he would be affected, the breathing at once becoming much obstructed, the cough gaining rapidly in force and frequency, and the attacks of dyspnœa becoming more and more severe, until orthopnœa would declare itself and he would have to pass the greater part of the twenty-four hours in a sitting position. Here, as with S. T—— and all my other patients affected with the disease, the heart became more and more affected with incapacity to pass the current of blood through its chambers, and so there ensued venous engorgements and dropsical affections. This heart failure plays a most important part in the later stages of illness, and in by far the greater number of those under my observations has been the immediate cause of death, through asthenia and syncope.

I will now deal with the question of the alterations in the lungs proper, which at all times are to be found in these cases. I would premise that the changes in these organs are not secondary to inflammatory attacks there, either as lobar or lobular pneumonias, but that they are from the first a prominent feature in the chest symptoms complained of by the sufferers. In the early stages of illness, occurring, for most part, many years before the patients are reduced to a condition of permanent invalidism, one finds on auscultation marked increase of duration in the expiratory breath sound, with a lessening of the volume of the respiratory murmur generally. It is very evident that the normal elasticity of the lung tissue is impaired. This impairment, once produced, remains as a permanent condition, and it needs only a catarrhal influence, whether atmospheric or irritant, to throw the whole breathing apparatus out of gear. I know a number of workmen who are sure to appear at my surgery on the first frost or prevalence of east winds, suffering from severe cough with difficulty of breathing, and these men are the ones affected in the way I have just described. Under the influence of these miserable circumstances the sufferers become, as a rule, despondent and bad-tempered. I am not disposed to regard this despondency as due altogether to their actual sufferings; on the contrary, I attribute it largely to the functional disorders of their digestive organs induced by the vascular disturbances there to which I have already adverted. Moreover, the very nature of the complaint, coupled with the fact that those affected are compelled to continue under the adverse influences by which it was contracted, are sufficient to account for much that is unsatisfactory in the results of treatment. When the bronchitis predominates, very satisfactory results often follow one's attendance, but in the lung disease proper drugging yields but very poor returns.

So far I have not spoken of the exciting cause of this chest mischief, and I will now deal with this matter. I find that the parts of the works which seem to be most injurious to those engaged in them are the calcining and the yellow metal departments. In the process of calcination or roasting, the rough copper ores which are in combination with different proportions of other metals, such as iron and sulphur, tin and arsenic, together with earthy matters, are heated in an appropriate furnace to such a pitch that the volatile ingredients are disengaged in the gaseous form, "whilst the metals that possess a strong affinity for oxygen become oxidised." Much dust also is flying about, and so a calcining furnace and its neighbourhood is a very rough corner of the works. The yellow metal workers suffer still more than the calciners, for the place in which they are working becomes at the moment of casting quite enveloped in fumes and particles of volatilised metal, which are necessarily drawn into the lungs when breathing. I may remark in passing that I have met with well-marked cases of "brassfounders' ague" amongst those yellow metal workers. But the injurious influences of the works are not limited to the calcining and the yellow metal departments; on the contrary, the whole range of furnaces at which the metal is smelted, and the mill in which it is rolled, all contribute to the general fund of irritation.

Now I come to the question of the duration of life in those affected with "copperman's chest." This is by no means short, although most of those who are sufferers by their occupations become prematurely old. It is no exception for men to live up to a good age, having been troubled with the various ailments I have spoken of for thirty years and onwards. The thing varies in degree, and although many men die at a comparatively early age from acute chest attacks grafted on chronic disease, a great many go on from year to year, suffering each winter from distressing coughs, shortness of breath, cardiac and gastric disturbances, &c., to such an extent that life is more a burden than a pleasure to them. I suppose the very conservatism of the pulmonary changes which form the product of the constant irritation to which they have been exposed serves them in good stead, and is a great bar to sudden and severe inflammations which would have the effect of terminating life. The keynote of the pathology of the subject is evidently irritation; and we all know what results when mechanical irritation affects the lungs and bronchial tubes: the former become affected with "a progressive fibrosis," whilst the latter take on dilatation and ulceration. The lung fibrosis becomes more and more confirmed; the "fibro-nucleated tissue [I now quote from Green] which constitutes it is developed from the walls of the alveoli, from those of the bronchi, and from the interlobular tissue; which new growth, as it increases, and from its tendency to contract, gradually replaces and obliterates the alveolar structure." Hence ensues permanent dyspnœa, aggravated at times and under various irritations into attacks of asthma. The very density of the lung, now occupied largely by fibrous tissue, is a bar to the presence of much blood in the parts, the capillaries being to a very great extent obliterated. Following this obliteration comes imperfect aeration of blood and all its concomitant troubles; whilst, on the theory of "collateral fluxion," the blood present in the body has to find some new channel of distribution other than its ordinary one, or submit to curtailment. We shall see that this last fact is well worth noticing, with a view to treatment directed against symptoms arising in consequence of it.

I have drawn special attention to the cardiac disturbance in these cases. It shows itself in the form of rapid and irregular action, and, in the later stages, by manifest incompetency to carry on the current of the circulation. On examining the pulse, it will be found to be irregular in force and rhythm—circumstances due, I take it, to disturbances of the vaso-motor nervous system. One can easily understand that the heart disturbance and incom-

Digitized by Google

petency are due to failure in coping with the extra difficulty it finds in propelling the retarded blood through the pulmonary capillaries, and that, just as in kidney cirrhosis, but in a different way, it is disturbed in its function. In kidney disease, hypertrophy of the heart often ensues; in these cases of interstitial pneumonia, due to copper smelting, the force of the heart's action is not augmented, but its frequency is, whilst the rhythm of its contractions is disturbed or abolished. May not the fact of the aeration of the blood being interfered with, and, through this disturbance of aeration, the general functional health of the body, have as much to do with enfeeblement of nervous control and heart contraction as the mere mechanical difficulty in propelling a blood current with an organ of ordinary capacity has? I cannot remember ever having met with a case of hypertrophy of the heart where there has been pronounced "copperman's chest"; on the contrary, in the majority of cases, I have found the condition of debility prevailing to which I have just drawn attention.

One can easily see, from the foregoing, that there is no royal road to *treatment* in the complicated state of "copperman's chest." To my mind, susceptibility plays a very important part here as in other diseases. I believe the majority of cases originate during the existence of a catarrh, and that the irritations have not much power of doing permanent mischief when the breathing apparatus is in a healthy condition. Acting on this theory, I do what I can to keep workmen affected with recent chest troubles at home, and on the funds of their clubs, as I regard an abstinence from work at such a time, in such an atmosphere as obtains in copper smelting, as a prophylactic measure of the first value. I cannot say that I have found any one drug to prove of especial value in treatment. I had hoped much from iodide of potassium, but have been disappointed. Belladonna, morphia, ipecacuanha, cod-liver oil, and digitalis are all serviceable in their turn, when indicated. The treatment, in fact, resolves itself after a while very much into one of combating symptoms; and the main point is to keep the patient as jealously guarded from adverse atmospheric influences as is possible. As with all people affected with organic visceral disease, chilling of the surfaces, whereby blood is diverted into the deeper-seated parts, is to be carefully guarded against; and it is a *sine qud non* in bad cases that the patient shall be kept in-doors during the prevalence of the cold or changeable seasons. The patients are most sensitive barometers, and, just as the column of mercury in a weather glass runs up and down with the varying atmospheric pressure, so they continually alter under the same influences. Box them up ever so much in comfortable quarters, they will still respond to the weather outside. The one special point in treatment is to act freely on the bowels occasionally. This gives marked relief, not only to the discomfort of flatulence from which they are prone to suffer, but to the very breathing itself. In bad cases where attacks of dyspnœa have prevented sleep, and when bromide and other soporifics have failed to give relief, a timely dose of jalapine or of white mixture has often proved a veritable sleep-inducer by tranquillising the system and allowing repose. It is well to bear this matter in mind, for the purgative often gives relief when not directly indicated.

Swansea.

CASE OF SLOUGHING OF THE SCROTUM, UNCONNECTED WITH URINARY EXTRAVASATION.

BY C. E. HARRISON, M.B. LOND., F.R.C.S.,
SURGEON-MAJOR, GRENADIER GUARDS;
AND
H. R. O. CROSS, M.R.C.S., L.R.C.P. ED.,
SURGEON, GRENADIER GUARDS.

IN connexion with the cases published by Mr. Morrant Baker under the above heading in THE LANCET of July 25th, 1885, and also of June 5th, 1886, the following notes may be of interest.

Private J. P——, aged forty-one, was admitted into hospital on the morning of June 4th, 1885. At the time of admission there was considerable swelling of the scrotum and perinæum, with a dark thin [illegible] of discolouration on the anterior surface of the scrotum. The appearance was very suggestive of extravasation of urine. The scrotum, however, was not tense, though much increased in size; the movements of the man's body as he was lifted into bed conveyed a tremulous motion to the œdematous scrotum. There was fulness in the perinæum, which was rather more tense on the left than on the right side. Pulse 120; temperature raised. Tongue clean; cardiac sounds clear, and the physical signs of the lungs normal. The urine contained rather more than a trace of albumen. The patient is a strongly built, well-nourished man, but has been a rather hard drinker. He stated that he had a fall on the buttocks on June 2nd whilst going downstairs, and that on the following day the scrotum commenced to swell. He had since then, he stated, had a little difficulty in passing urine, but there was no history of stricture. A medium-sized catheter (Sir H. Thompson's) passed into the bladder without difficulty. This was withdrawn and No. 11 passed readily. It was thought advisable to tie in the catheter for a time. He was ordered to have some warm fomentations applied to the scrotum, and to take tincture of cinchona with dilute nitro-hydrochloric acid. In the evening it was evident that the scrotum would slough. Twelve or fourteen incisions were made in the scrotum, which was tenser than in the morning. The œdema was spreading to the penis, where an erysipelatous blush was present. A large amount of serum, perfectly free from any urinary odour, drained away. Temperature 104·5°; pulse 122. Poultices applied to scrotum.

June 5th: Temperature 103°; pulse 105. The penis is more involved. Several incisions made. Evening temperature 103·2°; pulse 114. Fresh incisions necessary.—6th: Temperature 103·6°; pulse 112, rather small. Tenderness felt on pressure above the groins, inflammation spreading to the subcutaneous tissue of the abdomen. Ordered one grain of opium, to be repeated in six hours, with strong beef-tea, eggs, and brandy. Evening temperature 103·4°; pulse 112. The patient showing a tendency to be very drowsy, the opium was not repeated. An incision has been made above the right groin, and incisions also into the subcutaneous tissue of the penis. Warm hip-baths with Condy's fluid ordered.—7th: Temperature 101·7°; pulse 106. Patient's aspect improved. Portions of the skin of the penis have sloughed. Evening temperature 102·9°; pulse 112. Charcoal poultices applied.—10th: Temperature 101°; pulse 100. Yeast poultices ordered. Evening temperature, which has been lower for the last two days, has risen to 103°; pulse 107.—11th: Temperature 101·6°; pulse 112. Patient's general condition improved. Nearly all the sloughs have come away, comprising the scrotum (with the exception of a fringe of tissue on each side, which much resembles in its shape and irregular border a cock's comb), the septum scroti, and the loose subcutaneous areolar tissues of the perinæum. The two testicles, enclosed in their coverings of fascia, hang down completely denuded of cutaneous and dartos tunic. Evening temperature 102·9°; pulse 120.—12th: A little arterial hæmorrhage occurred from a vessel at the back of the wound, which was secured with a ligature. Temperature 101°; pulse 90. Evening temperature 101·4°; pulse 80.—13th: The surface of the wound is becoming clean, and looks healthy. Iodoform is now dusted over the surface. A liberal allowance of brandy and light nourishment ordered. Temperature 99·1°.—19th: Temperature still raised slightly at night. The discharge from the wound is decreasing. The incision above the right groin having closed, there is now some accumulation of pus. A drainage tube inserted; glycerine and carbolic acid applied as a dressing to the testicles.—24th: The fringes of skin are granulating from the bottom on the inner surface, and adhering to the testicles.—28th: The testicles appear much contracted, and are being gradually drawn up towards the groins. Granulations cover the cords and testicles.—July 1st: Deep-seated suppuration above the right groin, causing slight rise of temperature.—5th: Five skin-grafts were placed on the penis, which had lost a very considerable part of its cutaneous covering.—12th: Second grafting of four pieces of skin.—17th: Six of the grafts have taken. The wounds are healing fast.—27th: The patient is able to eat solid food, with a pint of ale. The wounds are dressed with sanitas. During the process of healing the testicles have gradually been retracted, and are now drawn up close to the external openings of the inguinal canals, and covered over by the thick adipose layer situated here. The fringes of skin left from the scrotum have been during the past ten days pressed over the wound by means of pads, and the

Digitized by Google

two granulating surfaces have united. A triangular surface is left covered with granulations between the edges of these fringes of skin.—30th: Two skin-grafts applied to the granulating surface. The testicles are now gradually coming down into the newly formed scrotum.—Sept. 14th: The wound is healed with the exception of a square half-inch.—30th: The patient was discharged from hospital, and shortly afterwards returned to duty.

At the present time (August, 1886) the man is in his usual health and performing his duties as a soldier. The urine is found on examination to be free from albumen.

Wellington Barracks, S.W.

PUERPERAL APOPLEXY IN A YOUNG WOMAN;

LIFE MAINTAINED FOR FOURTEEN HOURS BY ARTIFICIAL RESPIRATION.

BY N. WHITELAW BOURNS, M.D.

MRS. E——, aged thirty, engaged me to attend her in her first confinement, which she expected about the end of March. She was a rather thin, anæmic-looking woman, and a great sufferer from chronic rheumatic arthritis, causing distortion of the finger joints. She informed me that the articular trouble had been much better during her pregnancy; she otherwise enjoyed fairly good health. At 3.30 A.M. on February 18th I was called, and told by the husband, a medical man, that she appeared in her usual health up to midnight, when she retired to her bedroom, having entertained some friends during the evening. Her husband joined her about 1 o'clock, and found her complaining of pain in the epigastrium, for which she took a little bicarbonate of soda. The bowels had acted before going to bed, and urine had been passed freely. About 1.30 A.M. she complained of constant pain over the abdomen, and was given a grain of opium in a pill; but the pain continuing, a vaginal examination was made by her husband, and as he found the os externum dilated to the size of a shilling, he thought it well to send for the doctor and nurse. The patient was then begging for chloroform to relieve the continuous abdominal pain. I reached the room at 3.45 A.M., and found her quite unconscious, lying on her back, rather high in bed, with her left hand apparently supporting her head. On examination I found the os slightly dilated, and with some difficulty made out a vertex presentation. There was no vaginal discharge. Pulse about 90, and regular; respirations natural; pupils equal, not contracted, reacting to light. I carefully watched her for some little time, and saw that she continued in the same state, with occasional uterine expulsive pains, during which she held her breath, and moved her legs up and down in bed. As the urine voided before going to bed had been thrown away, I passed a catheter, and found the bladder empty; but upon withdrawing the instrument, a couple of drops of deeply blood-stained fluid escaped from its eye. Feeling alarmed at the condition of the patient, I sent for Dr. Clement Godson, and shortly afterwards found the pulse much slower—not more than 60 to the minute—and rather full; pupils equal, slightly dilated, and not reacting to light. No appearance of paralysis of the muscles of the face. The breathing for a few respirations was inclined to be stertorous, and at 6.15 A.M. she gave a couple of sighing inspirations, and then stopped breathing. No pulse at the wrist. The heart could be felt over the præcordial region, but the action was very feeble. I at once set up artificial respiration, and the heart soon began to improve, so that when Dr. Godson arrived, soon after 7 o'clock, he was able to count the pulse in the radial, and made it 96 to the minute. We discontinued the artificial respiration, but within two minutes the patient became markedly cyanosed and the pulse almost imperceptible. Artificial respiration was again started; hypodermic injections of ether and enema of brandy given, and the galvanic battery freely used. The fœtal heart was listened for, but could not be heard. Dr. Godson passed a catheter and drew off about three drachms of dark blood-coloured fluid; he found the os dilated to the size of a two-shilling piece. Enemata of peptonised beef-tea was given, and the respiration kept up by a staff of neighbouring medical men, who kindly lent their services. No change took place in the condition of the patient up to 2.30 P.M., when we had the advantage of a consultation with Drs. Playfair and Godson, and the diagnosis of cerebral hæmorrhage was maintained. However, artificial respiration was continued until past 8 o'clock, when reluctantly we had to admit that the case was hopeless, and on discontinuing our efforts life was soon extinct.

For the following post-mortem report I am indebted to Mr. Colby of St. Bartholomew's Hospital. Examination nineteen hours after death:—Rigor mortis well marked. Heart: Some excess of pericardial fluid, a patch of recent lymph as big as a shilling over the front of the ventricles near the apex. No valvular disease; no atheroma of the aorta. Lungs: Œdema of both lower lobes. Liver: Capsule stripped off easily in the neighbourhood of the right kidney. Kidneys: Some irregularity and thinning of the cortex. Surface smooth. Capsule of right came off very easily, and the organ was engorged. Ureters free. Bladder empty. Brain: Under the meninges and on the surface of the left hemisphere was a clot as large as a crown piece, covering the upper end of the fissure of Rolando; on the parietal region of the right hemisphere a similar but smaller clot. In the left hemisphere was a clot as big as a duck's egg, continuous with that on the surface, and lying outside the external capsule, but compressing both the basal ganglia and the convolutions. The right hæmorrhage was superficial.

There are, I think, several points of interest in connexion with the case. Had parturition actually set in before the hæmorrhage occurred? Again, were the uterine efforts in any way owing to the cerebral clot? I am inclined to think that, considering the aspect of the case before the loss of consciousness, and the condition of the os, the first step in the case was commencing parturition. Next as to the diagnosis; this was admitted by all to be a point of great difficulty, as the age and appearance of the patient, the onset of the attack, the absence of any paralysis, facial or ocular, and the fact of the catheter drawing off only a little sanguineous fluid, all point to other than cerebral causes. Lastly, the length of time life was maintained by artificial respiration is, I think, very interesting, if not unique, as there cannot be the least doubt that any interruption of artificial respiration between 6.15 A.M. and a few minutes past 8 P.M. must have resulted in immediate death. It would also be interesting to know how long life would have been maintained if sufficient relays of medical men could have been procured to continue artificial respiration. In conclusion, I may say that both Dr. Playfair and Dr. Clement Godson look upon the case as a most unusual one, and well worthy of being placed on record.

West Brompton.

A CASE OF

OVARIOTOMY, FOLLOWED BY SECONDARY INTRA-PERITONEAL HÆMORRHAGE; RE-OPENING OF THE ABDOMEN; RECOVERY.[1]

BY HENRY W. FREEMAN, F.R.C.S.I., L.R.C.P. LOND.,
SURGEON TO THE ROYAL UNITED HOSPITAL, BATH.

LIZZIE D——, aged twenty-two, a fine, tall, young, single woman, the eighth child of a family of nine, was admitted into the Royal United Hospital, Bath, on July 21st, 1886, with an abdominal tumour. She had menstruated painfully for five years, the menses having ceased four months before admission. She stated that a swelling on the right side of her abdomen had been noticed for fifteen or sixteen months, and it had gone on increasing solidly towards the left side, accompanied by some œdema of the legs. Her general appearance, however, was that of a healthy woman, and, but for the mechanical weight in carrying about the tumour, she had little to complain of, and had done her work as a domestic servant up to the day of her admission.

On examination, the abdomen was found to be occupied by a smooth, hard, semi-elastic growth, a little uneven at its upper margin, and extending from the *left* side of the pelvis to four inches above the umbilicus; dull all over on per-

[1] Read at the Bath and Bristol Branch of the British Medical Association, Dec. 9th, 1886.

Digitized by Google

cussion, with no definite fluctuation anywhere. The flanks were resonant, and the fingers could be carried between the tumour and the pubic rim. The abdominal circumference measured thirty-five inches and a half. Her excretory organs were healthy. The cervix uteri was pointed and pushed backward in the direction of Douglas's pouch; the uterus was fixed, the sound passing in to the extent of an inch and a half only. A rough, harsh friction sound was heard over the right lobe of the liver, and an extensive adhesion was diagnosed.

On Aug. 19th the patient was operated upon, under ether and antiseptically, and a large single solid cystoma was seen on opening the abdomen. An extensive adhesion was found over the right lobe of the liver, which was broken down and ligatured with chromic silk. The tumour was solid and unyielding, and before it could be raised from its bed free incisions were made and quantities of semi-solid gelatinous matter got away. Other small adhesions were treated in the usual way. The pedicle which involved the *left* ovary, *not* the right, was broad, thin, and so short that it was strained upon when the solid growth was moved in the abdomen. The pedicle was transfixed with the Staffordshire knot, clamped, and subsequently cut off with a bistoury. The peritoneal toilet was carried out by the aid of a Leiter's irrigator with warm water, and much sponging for cleaning out the abdomen was consequently avoided. An eight-inch Keith's glass drainage tube was inserted through the lower angle of the wound down into Douglas's pouch, and guarded antiseptically. Chromic acid sutures for the abdominal parietes were used as usual, and the patient was put to bed in an apparently satisfactory condition, with but little shock or collapse. Four hours afterwards, on visiting my patient, although the nurse reported favourably of her, a glance on removing the dark window-blind told me all was not right: the face was pale, pulse rapid, and the surface of the body was getting cold and clammy. On examining the tube and dressings no discharge was seen, but on carrying the rubber tube of a suction syringe through the glass tube straight into Douglas's pouch an ounce and a half of pure venous blood was brought up. Dr. Cave (the resident physician) quickly joining me, it took but a few seconds and a whiff of ether and chloroform to reopen the abdomen, when, to my dismay, we found the intestines were swimming in blood, and the whole abdomen filled with fluid and clot. Brandy was quickly injected into the rectum, the cavity rapidly cleared out, the pedicle seized and inspected, and the tied adhesions examined closely, but we could not make out the bleeding spot. When the stump of the pedicle was raised no venous oozing could be detected; when it was dropped back again into the abdomen oozing took place again and again into Douglas's pouch, but the blood came *not* from the stump. The pedicle was found securely ligatured; nothing came from it. On carrying a light into the pelvis, blood was seen to ooze from a small valvular rent in that portion of the left broad ligament between the stump and fundus of the uterus, but only when the pedicle was in a dependent condition and lying in the pelvis; it stopped at once as soon as it was raised and held up. Evidently a rent had been made in the pampiniform plexus of the left broad ligament, and it was at last picked up, transfixed in two places, and tied in halves. The abdomen was again minutely cleaned out with the irrigator, the wound closed, and the tube replaced; but the patient was pulseless and apparently moribund. A large wash-hand basinful of blood and clot had been cleared out of the abdomen. Iced champagne and peptonised milk with brandy, a teaspoonful every twenty minutes by the mouth, and nutrient enemata and suppositories by the rectum, were ordered, and in two hours, although blanched and restless, the pulse was felt beating feebly 168 to the minute, and she asked for sips of hot tea. Three hours after this vomiting set in, with thirst of course, but no headache or gaping. She dozed at short intervals during the night, and secreted four ounces of urine. Dr. Goodridge saw her with me at noon. Pulse 150; temperature normal. Strong doses of digitalis were advised. Retching, with constant vomiting, compelled us to abandon drugs by the mouth for a few hours; but on the morning of the second day, the pulse having gradually fallen during the night to 120, we gave her small doses of calomel and extract of opium by the mouth frequently, which brought away some bilious stools on the evening of the same day; she passed flatus freely, and expressed herself as feeling more comfortable. She took and retained her nourishment now. The rectum was washed out periodically to avoid tenesmus and septicæmic absorption. Her pulse fell on the fifth day to 108, the temperature not exceeding 100°; the glass drainage tube was emptied of about an ounce and a half of pure sweet serum, and on the sixth day it was withdrawn and the wound closed with stout silver wire. The parietal sutures were removed on the tenth day, except the silver one at the site of drainage, and she was then practically convalescent, with a pulse of 100, and temperature normal. Only one parietal suture suppurated, and that was due to the China twist not being prepared. She subsequently did well, sat up at the end of the month, and left the hospital five weeks after the operation. She menstruated six weeks after the operation and monthly since, without discomfort. The tumour weighed 10 lb.

Remarks.—It perplexed me very much at the time to explain how that small rent took place in the left broad ligament which caused all this hæmorrhage; and I believe when the solid weighty tumour was lifted out of its bed, the pedicle being thin, short, broad, and ribbon-like in structure, it was pulled upon and split before the ligature was applied. The clamp succeeded the ligature, it will be remembered, as previous clamping might have caused the rupture when the ligature knot was being tied. The ligature stump when dropped down bled, and when held up stopped, giving us the impression it was the cut pedicle that bled; but it was *not* so. A vein of the left ovarian or pampiniform plexus had been opened obliquely, and Rivington in the *Journal of Anatomy* has shown that these veins of the broad ligament communicate freely with the uterine plexuses and sometimes have imperfect valves; but on the *left* side it is commonly absent, the valve being found in the left renal vein, about a quarter of an inch from the entrance of the former vessel; and further, Bland Sutton, in demonstrating the remains of the meso-nephros or Wolffian body, in his splendid work on the Evolution of Pathology, points out, that this curious plexus of veins called the pampiniform plexus, are, in reality, the dilated tortuous venules, which originally administered to that very curious structure the paroöphoron. The bleeding was entirely venous, but the coagula were fragmentary, small, and thin, contrasting markedly with uterine clot in parturition. How far the interference with perfect coagulation is due to a closed serous cavity or to the lymph spaces of the peritoneum with their open stomata I am not prepared to say. We closely examined the right ovary that remained, and it was found shrivelled up, and atrophied like a piece of old wash leather; yet the patient has menstruated freely several times since the operation, which leads one to consider how far the Fallopian tube plays an active part in this phenomena.

Now, as to the character of this semi-solid tumour. Bland Sutton has so recently arranged his facts that it is difficult to dispute the origin of parenchymatous ovarian cysts from corpora lutea, and he describes them as arising in this way from infancy up to the end of sexual life, and ripe follicles are frequently present in the ovary before birth. In vol. xxxvi. of the Pathological Society's Transactions he describes the transverse section of a mare's ovary, showing a corpus luteum, the interior having broken down into two small cysts, and this explains the origin of many of those cysts so common in the ovaries of full-grown mares. It is a curious fact, and I have seen it often during the past ten years, that nearly all mares, after they attain the age of ten or twelve years, have cysts present in their ovaries, which probably arise from corpora lutea. You may demonstrate this statement more commonly even in cows than horses, and the primitive condition in the former animals of the ducts of Gaertner, the analogue of the vas deferens in the male, explains the frequent presence of cysts about the upper portion of the vagina. I have a strong impression the colloid tumour of this woman arose from a corpus luteum. Again, what becomes of the ligatured pedicle after the operation? It becomes encysted, we admit; lymph or clot forms on its surface; but how is it nourished, or does it slough? I shall risk the view that the everted peritoneum *above* the ligature bends downward, and joins the nearest point *below* the ligature, and so maintains its vitality. In Sir Spencer Wells's statistics we find that in his first 500 operations there were *no* deaths from hæmorrhage, but twenty from exhaustion, while in the second series of 105 there were only eight from exhaustion and two from hæmorrhage; but he adds the probability that some of the first series of deaths were also partly due to bleeding, but the fact was not established by examination. Keith's mortality from shock

Digitized by Google

and hæmorrhage was 3·6 per cent. Lawson Tait does not mention any deaths from hæmorrhage in his later statistics.

I wish to draw attention towards the use of the glass drainage tube in all abdominal sections, and I am aware that in the hands of Mr. Lawson Tait drainage is never used if the abdomen can be properly cleansed and dried. Keith still places great reliance on his Koeberlé's drainage tubes. Spencer Wells doubts their success, although I am under the impression he drained the peritoneal cavity in his earlier operations. Mr. Knowsley Thornton considers them only necessary in 2 per cent. of cases done antiseptically, and 10 to 15 per cent. of cases without antiseptics. Quite recently, however, Mr. Lawson Tait has pointed out how remarkable is the influence of the drainage tube in arresting hæmorrhage into the peritoneal cavity: for if the cavity is kept dry by frequent withdrawal of the blood, the bleeding, as from torn pelvic adhesions, will stop; but if drainage is not kept up the bleeding will probably prove fatal. This is a strong point in favour of the tube. In my own cases of laparotomy I have been struck with the little irritation produced by the glass tube in the abdomen. It has been kept it in for eighteen days in an hysterectomy and for a week in an ovariotomy; but care must be taken that the end drops easily into the bottom of Douglas's pouch, and is not displaced above the promontory of the sacrum. In the case recorded the glass drainage tube saved the patient, by immediately confirming the suspicion of secondary hæmorrhage, and minutes meant in her case her existence. In complicated cases with purulent cysts the utility of the thing is admitted; but for the beginner in abdominal surgery, we would venture to say, Use Keith's drainage tubes, and always do so if in doubt. It will be a safeguard to your patient and a comfort to you for the first hours after the operation, as it brings the doings of the peritoneal cavity within touch of your special senses.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CASE OF CHRONIC INTERSTITIAL NEPHRITIS.[1]

BY C. H. ROBINSON, F.R.C.S.I.,

MEMBER OF THE COURT OF EXAMINERS OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND, LECTURER AT THE LEDWICH SCHOOL OF MEDICINE, ETC.

THE lady, aged fifty-five, whose case is described in the following brief notes, was under my observation for years, the signs of the malady from which she suffered commencing with hypertrophy of the heart, followed by albuminuric retinitis, epistaxis, and finally cerebral hæmorrhage, which terminated fatally last November. In the autumn of 1885 the sight of her eyes became considerably affected, and on examination by the ophthalmoscope hæmorrhagic retinitis of both eyes was found to be present. At this time the urine passed was copious in quantity, pale in colour, of specific gravity 1006, and on one occasion only was I able to detect any albumen, and then only the merest trace. At various intervals it was carefully examined, with a negative result. Under appropriate treatment (which included the administration of the perchloride of mercury in combination with the iodide of potassium, the bowels being kept open by occasional doses of Friedrichshall water and a spare dietary enforced), the sight after several weeks was restored, and the specific gravity of the urine gradually became normal. In January, 1886, I was sent for in consequence of a severe attack of epistaxis, which was arrested by plugging the anterior nares and applying an ice-bag over the cardiac region. In October of the same year I attended her for uræmic vomiting, and in the following month she called at my house about three o'clock, and when leaving complained of a numbness in the right leg. She wished to proceed into town, where she had some business to transact; but I persuaded her to go into the waiting-room, and in a couple of minutes there was complete anæsthesia as high as the knee. She remarked that she had dreaded this, and expected to be paralysed. I had to leave her for a few minutes, and then found the right arm paralysed as well as the leg, also the face on the same side. Her articulation now became impaired, but she could put out her tongue, which was directed to the right side. I had her removed to her own house, where, on arrival, although unable to speak, she appeared to be in a semi-conscious state. About seven o'clock the same evening she was perfectly unconscious; the pupils contracted; pulse 78; temperature 95°; respiration fairly quiet, occasionally stertorous. During the night she exhibited Cheyne-Stokes' respiration; the pulse gradually got higher; the temperature went up to 100°, then to 102°; while the face and neck were greatly congested. The eyes, which were now dilated, had that peculiar fixed stare so characteristic in serious attacks of cerebral hæmorrhage. The right arm was very rigid, but gradually relaxed. Death took place about thirteen hours after the first seizure, being preceded by a violent trembling.

Some, perhaps, might regard the fatal result in this case as due to uræmia, in which occasionally hemiplegia has been shown to occur;[2] but the absence of convulsions and the rapid increase in the temperature would, I believe, show such an opinion to be erroneous. Albuminuria may exist, it is well known, without nephritis, but the converse of this is comparatively rare. Where no trace of albumen can be detected in the urine, but the general symptoms point to interstitial nephritis being present, the test recommended by Feltz and Ritter, as modified by Prof. Bouchard, it is said will decide the matter.[3] The urine of a healthy person when introduced into the circulation of the rabbit by injection into the veins of the ear kills the animal in the proportion of 50 grammes per kilogramme of weight. But that of albuminuric subjects can be tolerated in much larger doses, and in one case mentioned by M. Dieulafoy a rabbit of two kilogrammes, for which a toxic dose of healthy urine would be 100 grammes, exhibited no discomfort until 260 had been injected, and even then recovered.

NOTES ON A CASE OF HÆMOPERICARDIUM FROM RUPTURED CORONARY ARTERY.

BY J. W. BATTERHAM, M.B. LOND., F.R.C.S.

ON March 9th, 1887, I was called to a lady who had died suddenly. The following was the only history obtainable from the friends of the deceased. She was seventy-five years old, and had suffered for "some time" from "slight fits," in which she "struggled" and lost consciousness for a few minutes. These fits were usually preceded by sickness. About noon on the day of her death she complained of pain in the left mammary region, and took a Gregory's powder. She then had lunch, which consisted only of a little beef-tea. Her servant coming into the room about an hour after lunch found her sitting in a chair dead. The deceased's face was pallid. She appeared to have vomited just before death, as some brownish fluid containing gritty particles (apparently the beef-tea and Gregory's powder) was seen staining her chin and the front of her dress.

The necropsy, performed twenty-four hours after death, showed the heart enveloped in about four or five ounces of dark clot. There was no rupture of the heart or great vessels. On the posterior surface of the heart was a slight subpericardial ecchymosis, covering an area about the size of half-a-crown, situated on the interventricular groove about an inch from the apex of the heart. A fine aperture with ragged edges was discovered in the pericardium covering the centre of this ecchymosis. On vertical section through this aperture, a few small clots were seen in the muscular substance of the hypertrophied left ventricle. The largest was about the size of a small pea, and was situated immediately beneath the minute aperture in the pericardium above described. The coronary arteries were tortuous and thickened, their coats containing numerous calcareous plates. On dissecting out these vessels, the left, after running down the anterior interventricular groove and turning round the apex to the back of the heart, was found to terminate in two main offsets, which surrounded the area of hæmorrhage. Two small twigs were traced into the clots,

Digitized by Google

but were of too small size for any rupture of their walls to be detected. These, I imagine, were the chief source of the hæmorrhage. The heart weighed 12¾ oz. Its muscular tissue was firm, and of good colour. The thickness of the right ventricular wall was one-eighth of an inch, that of the left (at its thickest part) half an inch. The valves were normal in appearance; the aorta was healthy. The other thoracic and the abdominal viscera were normal, with the exception of the kidneys, which were small, red, and granular, and showed a marked diminution in the cortical substance. The head was not opened.

From the post-mortem appearances, it may, I think, be concluded that the "fits" from which the deceased had suffered were probably of uræmic origin. The pain in the chest felt for a few hours before death may have been due to the rupture of fine branches of the left coronary artery into the myocardium, while the perforation of the pericardium and subsequent hæmorrhage into the pericardial sac, resulting in fatal syncope, may have been induced by an act of retching.

Hæmopericardium is not a very uncommon condition. References to between eighty and ninety cases may be found in the first thirty-five volumes of the Pathological Society's Transactions. The most frequent causes are rupture of the heart or aorta, occasionally from violence, but more commonly the result of disease. Seven cases due to rupture of an aneurysm of a coronary artery are referred to in vol. xxii. of the Transactions. Scurvy has also given rise to hæmorrhage into the pericardial cavity. On reference to Neale's Digest, I find that a case of hæmopericardium arising from a ruptured coronary artery is narrated in the *Medical Times and Gazette* for 1862 (vol. i., p. 317). In this instance the patient, a woman aged sixty, lived six days after the appearance of the symptoms, of which præcordial pain, dyspnœa, a small, frequent, but regular pulse, and coldness of the extremities appear to have been the chief. A case of purulent pericarditis in which a rupture of a coronary artery was found is quoted in Ranking's Abstract for 1861 (vol. ii., p. 85).

St. Leonards.

OTITIS MEDIA HÆMORRHAGICA.

By K. B. BULLEL, M.D.

CASES of pure and simple otitis media hæmorrhagica I think, are rare. Dr. Roosa mentions two cases, and Burnett only makes a passing allusion to the disease in his work on Diseases of the Ear. This is in itself a sufficient inducement to me to place the following case before the profession.

Mrs. C ——, aged forty-two, mother of nine children, and in a fair state of health, was placed under my treatment for an acute attack of pain in the left ear. Previous history: She had been suffering from the pain in the ear for the past ten days. The pain at first was of an intermittent nature and confined to the ear only. For the last two days it had been very severe, constant, and radiating all over the left side of the head and face. She complained of a feeling of fulness and acuteness of hearing on the affected side. The act of mastication and deglutition aggravated the suffering. The parts were very sensitive to touch. There was occasional paroxysmal aggravation of the severity of the pain. Along with these symptoms there were pyrexia, restlessness, and insomnia. On examination I found the left tympanic membrane uniformly congested and slightly bulged at the anterior and inferior quadrant. The right membrane was slightly in-drawn, and the naso-pharynx congested. The severity of the pain and a bulged appearance of the membrane induced me to suggest the operation of paracentesis, with a hope that that would relieve the suffering of the patient. The operation was performed at once. To my surprise, there was a gush of blood through the puncture in the membrane and the side of the nose, and nearly two drachms flowed freely. The intensity of the pain and sense of fulness were immediately relieved. From this time until complete recovery of the patient, which took nearly a week, not a drop of blood or muco-purulent matter escaped through the puncture in the membrane; the latter healed up in five days. Subsequent examination of the urine showed no trace of albumen in it. It is nearly four weeks now, and on examination of the ears I find no trace left as to where the membrane was punctured. In my opinion this case can be called a pure and genuine "otitis media hæmorrhagi ca."

Bombay.

CASE OF PLACENTA PRÆVIA.

By B. WALKER, L.R.C.P. ED.

ELIZABETH B——, aged thirty-three, has had seven children, of whom two only survive, the rest having died in infancy, at ages varying from two weeks to three years and a half. Two of these were born at the eighth month. There was no history of syphilis, and no hæmorrhage had occurred at previous labours. She had reached the seventh month of pregnancy, which had advanced normally. She went to bed as usual, and on awaking at 1 A.M on April 15th found the bed very wet. A neighbour was called in, and I was with her in half an hour after her awaking. I found her in a pool of blood on the bed; she must have lost about a gallon, for it had sunk through the mattress and deluged the floor, and her nightdress was saturated up to the armpits. On examination, the vagina was found to be filled with clots, and blood was flowing freely. The os was about the size of half a crown, and complete placenta prævia was present. Introducing the hand into the vagina and detaching the placenta, a vertical presentation was found, and with two fingers in the uterus and the right hand on the abdomen, combined version after Braxton Hicks's method was quickly and easily performed, and a foot brought down, thus plugging the cervix and causing the hæmorrhage to cease, the whole being done in five minutes. The woman was left comfortable on the bed, a dose of ergot and strychnine having been given, for there had been no expulsive pains hitherto. At 9 A.M., as far as labour was concerned, things were *in statu quo*. On calling at 1 P.M. I found the woman delivered (child stillborn) and the placenta expelled without any hæmorrhage. The woman made an uninterrupted recovery.

This case is very like the one recorded by Mr. Taylor in THE LANCET of April 30th (p. 875). The only object in adding this is to call attention to the long time (nearly twelve hours) before delivery was effected after version. After bringing down a foot, and the hæmorrhage having ceased, it seemed much safer to leave nature to finish the delivery than by traction on the child to empty a uterus which had shown no signs of physiological action—to empty it, and possibly to reawaken the hæmorrhage. In some cases the life of the child, though only at the seventh month, may be a consideration, but in this instance the mother's safety was of paramount importance, and would be in most cases, and entitled to the first place. The patient had, besides, an interesting history. In October, 1882, she had the lower half of the left scapula removed for a sarcomatous growth (her mother died at the age of thirty-seven from "internal tumours"), leaving her an arm little impaired for use. (See THE LANCET, vol. i., 1885, p. 203.) About three years ago, on becoming pregnant, a large ulcer—or rather two—and fungating growths, larger than an orange, attacked the outer side of the right calf. They healed quickly when she was put to bed. When pregnant again, seven months ago, another deep ulcer formed outside and behind the external malleolus. This lasted through the pregnancy, but is now reduced to one-half its size, and healing rapidly; besides this, an ugly sore formed over the sternal end of the right clavicle, which healed after a time. On each occasion it was feared the sarcomatous growth was reappearing, but the termination of pregnancy has hitherto been followed by the quick disappearance of the sores. The growth removed consisted of round cells with one large or two smaller nuclei, and of unipolar nucleated cells.

Spondon.

NOTE OF A CASE OF SUDDEN DEATH FROM PULMONARY APOPLEXY.

By W. HENRY KESTEVEN, M.R.C.S., L.S.A.

R. F——, aged sixty-five, was found lying on his left side on a staircase, with his head crushed against the wall and bent upon his right shoulder. At an examination of the body, made seventy-five hours after death, the brain was found to be healthy, though somewhat congested. The heart was healthy, and contained a small quantity of fluid blood in the left ventricle; none in the right. The lungs were adherent to the walls of the chest, and extensively infiltrated with tubercular deposits. The trachea and both bronchi contained blood. The source of this blood was

Digitized by Google

found to be in the left lung, the whole of the interstitial tissue of which was charged with extravasated blood. No distinct cavity or large clot was found in the lung, nor was it possible to find the vessel which had given way, though several branches of the pulmonary artery were traced. The bronchial tubes and tubules were full of blood. No blood had escaped from the trachea into the mouth or into the pharynx.

The case seems to be one of those described by Niemeyer as causing death suddenly, before hæmoptysis can occur, by blocking up the bronchi with blood and so suffocating the patient. It is recognised by the author just named as a very rare form of disease.

VICTORIA HOSPITAL FOR CHILDREN.

TWO SUCCESSFUL CASES OF OPERATION FOR CLEFT PALATE IN CHILDREN OF TWELVE MONTHS OF AGE; REMARKS.

(Under the care of Mr. H. H. CLUTTON.)

THE age at which operations for the cure of cleft palate should be undertaken has caused considerable discussion in the past, and there is still much diversity of opinion about it. The operation has been performed on a child of only four days old, but unsuccessfully, and it is not often attempted on children of twelve months old, and could only be successful in such cases as are here recorded. We agree with Mr. T. Smith's remarks:[1] "None but very general rules can be laid down as to the best time for operating, since each case must be judged on its own merits, and every surgeon will be guided by the results of his own experience." We would refer our readers to Mr. Clutton's remarks on the cases.

The first case (for the notes of which we are indebted to Dr. Moline, the medical registrar) was a girl of twelve months old, who was admitted in August, 1886. She was a healthy-looking, well-nourished baby, brought up by hand, as she could not take the breast. The cleft involved only the soft palate, and there was no other abnormality. On Sept. 2nd, the infant being under chloroform, the edges were pared and brought together with fine silk sutures. A lateral incision, chiefly through the pillars of the fauces, was made on each side to relieve tension. On Sept. 8th a few of the sutures were removed under chloroform. On the 15th the remaining sutures were removed in a similar manner. The palate was entirely healed and closed, with the exception of a small aperture near the hard palate. She left the hospital a few days afterwards. When seen again a few months later this opening had closed, and the line of union was scarcely perceptible, the uvula even having its natural form. The mother also said that the baby's cry had a much more natural sound than it had before the operation.

The second case, for the notes of which we are indebted to Mr. Wills, the house-surgeon, was a boy of eleven months of age, who was admitted on Jan. 17th, 1887. This was not such a healthy-looking child as the last, and was therefore kept in hospital on careful diet for a month before attempting any operation. With care the infant could take the bottle, but the food easily returned through the nose. The child had no other deformity, nor was there any history of this or any other abnormality in the family. The cleft involved the hard palate and a very small portion of the hard. The two halves seemed fairly thick, and not too far apart. On Feb. 10th, the child being under the influence of chloroform, Mr. Clutton pared the edges, and, finding that part of the cleft which involved the posterior edge of the hard palate too fixed to be successfully brought together by the simple operation, made a lateral incision on each side close to the gum, and raised a muco-periosteal flap from the bone, by the method generally known as Langenbeck's. The whole cleft was then very easily united by fine silk sutures. The pillars of the fauces were partially divided with a pair of curved scissors, as in the previous case, to relieve tension, and the operation was concluded on Feb. 20th. The sutures were all removed under chloroform, when the palate was found perfectly united from one end to the other.

Remarks.—It is obviously a great advantage, if the voice is to obtain its natural sound, that the operation should be done at as early an age as possible. If, however, it fails, any subsequent operation is made more difficult. It is, therefore, of great importance that only the simplest cases should be undertaken at this early age; and even amongst these success will greatly depend upon the thickness of the divided palate which is to be united. A healthy child at twelve months of age may have the simplest cleft in its palate, involving only the velum, and yet the tissues on each side may be so thin as to give a very poor prospect of success after operation. The circumstances which induced Mr. Clutton to operate at so young an age in these two cases were—the simple character of the cleft, the abundance of the tissue on each side, which would afford a thick bond of union, and the healthy condition of the children. The nursing after the operation which the child is likely to obtain has also to be considered, for with constant crying success is impossible. These two children were scarcely out of arms during the ten days succeeding the operation, and the success that was thus obtained speaks volumes for the care and trouble which was devoted to them by the nurses at the Victoria Hospital.

LEEDS INFIRMARY.

RUPTURE OF BLADDER; OPERATION; DEATH FROM PERINEAL HÆMORRHAGE; REMARKS.

(Under the care of Mr. T. PRIDGIN TEALE.)

FREDERICK S——, aged twenty-five, was admitted on Dec. 6th, 1883, having been violently assaulted two hours previously. He had been kicked in the abdomen and perineum during a quarrel, and when admitted complained of pain in the lower part of the abdomen and of inability to pass urine. There was tenderness of the abdominal wall, with tension of muscles, but no visible bruising at either seat of injury, and the patient was under the influence of alcohol. The retention was relieved by a No. 10 catheter, a few drops of blood preceding the flow of urine. The catheterism was repeated twice at intervals of six hours. There was, moreover, such an absence of collapse or alteration of look, pulse, or temperature, that the nature of the case was not suspected by the resident staff. On the following morning he was seen by Mr. Teale, who, observing a tympanitic abdomen, with dulness of the flanks, and being told that the more recent catheterism had only drawn off an ounce or so of urine, suspected rupture of the bladder.

At midday, after consultation with his colleagues, who agreed in the diagnosis of ruptured bladder, Mr. Teale operated. Having first opened the perineum in the median line and introduced into the bladder an indiarubber drainage tube, cut short at the wound, and stitched to its edges, Mr. Teale opened the abdomen between the umbilicus and pubes. A large quantity of pale straw-coloured fluid was found, in which the intestines floated freely, and without any trace of inflammation or congestion. At first the rent could not be seen or felt, owing to the collapsed state of the bladder, but on injecting through the perineal drainage tube a weak solution of carbolic acid a vertical rent was detected in the posterior surface of the bladder, not far from the apex, and fully an inch in length. The rent was closed by six fine catgut sutures, so inserted as to bring the peritoneal surfaces into contact without perforating the mucous surface, and the abdominal wound was closed without the insertion of any drainage tube. There was more oozing of blood from the peritoneal wound than usual, and shortly after Mr. Teale left the hospital Mr. Robson was called to the patient, who explored and then plugged the perineal wound. Some hours after there appeared to be some fresh oozing of blood, and the man became alarmingly anæmic from loss of blood, and died the next morning at seven o'clock.

At the post-mortem examination, the rent in the bladder

Digitized by Google

was found to be perfectly water-tight, and there was no peritonitis.

Remarks by Mr. TEALE.—The hæmorrhage from a simple median perineal wound was so unusual that one can only look upon it as an unfortunate coincidence, possibly the result of the kick in the perineum, of which no visible bruising gave warning. In another case of ruptured bladder, I should not think it necessary to insert the perineal tube, partly because the recent experience of others shows that such a course is not needed, and partly because it is a question whether on the whole suprapubic drainage would not be more satisfactory.

SAMARITAN HOSPITAL FOR WOMEN, NOTTINGHAM.

CASES OF ABDOMINAL SECTION; REMARKS.

(Under the care of Dr. TRUMAN.)

CASE 1. *Parovarian cyst.*—Jane S——, aged twenty-four, was admitted on May 19th, 1886. The menstrual periods commenced at the age of fifteen, and were painless until the last four or five years. The nature of her work requires frequent exercise of her strength in lifting heavy weights. Owing to pain in the lower part of her body she has been unable to go to work for the last six weeks.

On examination per vaginam, there was found a rounded swelling in the right lateral fornix, the size of a cocoanut, perfectly resistant and unyielding to pressure. Uterus pressed against the os pubis; its cavity not lengthened. The swelling felt solid, and it was suggested that it was due to a pedunculated myoma. In reference to this, Dr. Walter mentions the close resemblance of the physical signs, in a case of parovarian cyst, to those caused by a myoma attached to the posterior wall of the uterus. In the present case, however, the normal length of the uterine cavity, the absence of metrorrhagia, &c., pointed rather to the existence of a small ovarian cystoma.

An operation was performed on June 15th. In the right half of the pelvic cavity, and not at all rising above the brim of the pelvis, was a unilocular cyst, perfectly unadherent, and with a long narrow pedicle crossing over to the left side of the uterus. By aspiration were removed twenty fluid ounces of a perfectly clear and white liquid, of specific gravity 1006, containing neither fibrin nor albumen, but abounding in chlorides. The cyst was then drawn out, and the pedicle, three-quarters of an inch in diameter, secured by the Staffordshire knot and divided, when it was seen to spring from the *left* broad ligament, the cyst having fallen over into the *right* half of the pelvic cavity. The ovaries were healthy, and were not removed.

The patient made a good recovery, and was discharged on July 10th. She is in full work, and menstruation has been painless since.

CASE 2. *Dysmenorrhœa.*—Mary H——, aged thirty-two, was admitted on July 21st, 1886. The menstrual period began at fourteen. She has had severe dysmenorrhœa for eight or nine years, and was latterly dismissed from one of the metropolitan hospitals as incurable. The periods are regular, lasting seven days, with great loss, small clots being frequently observed. The pain never ceases in the intervals, but is intensified at the periods. The patient has great difficulty in walking a hundred yards, and this always increases the pain. She has been unable to work at all for the past two years, and is thus, much against her will, dependent on her friends for support. The situation of the pain is the left ovarian region, and this pain is increased if she lies on the left side.

On examination, the uterus was found slightly retroflexed. In the situation of the left broad ligament was a swelling the size of a walnut, freely movable, and exquisitely tender, nausea being caused when it was pressed between the two index fingers, one internal and one external. There was no tenderness. In the right ovarian region there was no pain except in the above-named spot.

On July 24th an operation was performed. The appendages were removed on both sides; the left ovary was enlarged and becoming cystic.

The patient was discharged cured on Aug. 24th. After a time spent in recovering her strength, she returned to work. She can now walk a couple of miles, and can work, if necessary, for fourteen hours a day. Although both ovaries were completely removed, there is a discharge of blood every month unaccompanied by pain.

CASE 3. *Hæmatosalpinx* (?).—Mrs. H——, aged thirty-two, was admitted on Dec. 7th, 1886. Has had four children; no miscarriages. First labour ten years ago; forceps were applied for five hours and a half. She was in bed for two months afterwards. Ever since has had more or less pain in the right iliac region. Has also had four attacks previously to the present one; these attacks came on suddenly and kept her in bed for three or four months. Her last child, fourteen months old, is at the breast. For the last eight months Mrs. H—— has menstruated regularly, and the periods have been longer than usual. A month ago she had sudden pain in right hip and pubic region, with vomiting and faintness; has been in bed since. Has had great difficulty in emptying the bladder.

On examination, the cervix was found jammed close to the pubic bone; the cervix was that of an unimpregnated uterus, but with a deep laceration. The right half of the pelvis was occupied by a tense, fluctuating tumour, continuous with a swelling above the pubes. This tumour stretched over to the left side, but the left half of the pelvis was not so closely filled up as the right. There was great tenderness to touch externally and internally. Temperature 100·2°. An operation was urgently needed on account of the partial blocking up of the urethra. This, however, had to be deferred; the woman was suckling, and the sudden weaning of the child made her very feverish. Pain was considerable, and had to be combated by opium. On re-examination on Dec. 29th, it was seen that the abdominal swelling was larger, and that, in addition to steady increase since the 7th, it had rapidly increased during the past forty-eight hours, and the woman was losing colour. There was marked dulness in the hypogastric region, and that mostly on the left side. The swelling felt per vaginam when first seen was principally on the *right* side; it was now on the *left;* and to the extreme left of this elastic swelling was felt a more resistant body.

The diagnosis was not very clear, but seemed to be one of three things: an ovarian cyst, with twisted pedicle, and consequent hæmorrhage into its cavity; an extra-uterine fœtation; or a hæmatosalpinx, the latter accounting the more readily for the history of four preceding attacks, if small hæmorrhages be supposed to have taken place. It was evident that hæmorrhage was actively going on at the present time, and the operation was performed on Dec. 30th. The pelvic cavity exhibited the following condition of things. The left half was occupied by a large swelling, consisting mainly of blood clot. The uterus was enlarged about three-quarters of an inch in all three dimensions. Between it and the rectum was the tumour, semi-fluctuant, and from three to four inches in diameter; by its upper surface it was free, but by the other surfaces it was adherent. The wall of the tumour was formed of (1) a strong, thick, fibrous investment, so firmly adherent to the bowel that it had ultimately to be separated by the knife, and passing upwards to the left cornu of the uterus, where it showed a large, ragged rent, and (2) of a layer of plastic lymph, which limited the contents of the tumour. This layer broke down with a touch and blood clot escaped. The finger was passed round the tumour and adhesions were pretty easily broken down. The solid part of the tumour sprang from the left cornu, and apparently was the left ovary; it was ragged and torn, and contained a cavity two inches across. The rest of the tumour consisted of blood clots and dark fluid blood. The blood clots were of two kinds, fresh and red, and old and decolourised (fresh blood coinciding with fresh pain and swelling on the 28th and 29th). In these clots were found a membranous cyst, very thin, and about three-quarters of an inch in diameter, and two small bean-shaped bodies half an inch to three-eighths of an inch long. The clots were cleared away, and the part of the growth springing from the uterus tied and removed. That part of the fibrous investment that was adherent to the bowel was tied and divided, leaving a margin half an inch deep attached. The posterior surface of the uterus was left freed, but covered with a rough layer of lymph. A glass drainage tube was inserted to the bottom of the posterior cul-de-sac.

The case went on well. The drainage tube was removed on Jan. 3rd, and the patient discharged on Feb. 1st.

Remarks by Dr. TRUMAN.—A question arose whether this might not have been a case of early tubal pregnancy. Dr. Handford, physician to the Nottingham General Hospital, most kindly examined the relics for me. He says: "All the tissues, besides the clot, are so infiltrated and sodden with blood

Digitized by Google

that it is unusually difficult to recognise the parts. I have made some sections, but the nature of the material is very unfavourable for making good sections. In the first place, I have failed to find anything fœtal, unless the small sac, which you suggest formed the envelope of the embryo, is of that nature. I would suggest that a sac that size could not be part of an ovum more than from four to six weeks old, and that the outer surface should be most distinctly shaggy and villous from the villi of the chorion. I do not think that at that early period the amnion would separate from the chorion so as to form a smooth surface. But if it is not a fœtal envelope, I cannot say at all what it is. The two bean-shaped bodies are undoubtedly not fœtal. They consist, in greater part, of blood clot; there is no trace of the cellular structure which makes up the whole of the early embryo, and there is a small quantity of adult adipose tissue which finds no place in the embryo till much later. The large mass with the peritoneal covering, and large cyst with an irregular mass projecting into it, I take to be explicable as follows:—The irregular mass projecting into the cyst seems to be an ovary much torn up and damaged by interstitial hæmorrhage. I cannot find any Graafian follicles, so that I cannot be sure; but at any rate, I can say that the tissue is adult, and not fœtal. There is much fibrous tissue, both white and elastic, and a considerable number of non-striped muscular fibres, with many large bloodvessels. I think I can trace going to it the round ligament, and the Fallopian tube, the extremity of which has, I conclude, taken part in forming the cyts into which the ovary projects. I would suggest as not unlikely a tubo-ovarian pregnancy, rupturing at about four to six weeks. At this time the ovum would be very small, and the embryo, being entirely cellular, would easily become disintegrated."

CASE 4. *Ovaritis.*—Mrs. T——, aged thirty-one, was admitted on Jan. 7th, 1887. Has always been regular, and the periods were painless up to her marriage, three years previously. Has never been pregnant. Three weeks after marriage had severe dysuria and white discharge; this lasted three weeks. Ever since then has had, a week before the period, swelling of the breasts, with secretion of clear liquid. This goes off when the menses appear. Periods since marriage have come on every three instead of four weeks, but the duration has gradually decreased. Has had ovarian pain also, and this has much increased in the last twelve months. Has never done a day's work without pain since three weeks after marriage. Pain in lower part of the abdomen was at first relieved by lying on the abdomen, or by elevating the knees; but this is not the case now. For the last twelve months she has been unable to do her household work; any slight jar, such as walking, brings on the pain. Sexual intercourse is most painful, and she is unfitted for all her duties. There is an adenoma of the left breast, and in both breasts there is an abundance of clear serous fluid, in which colostrum corpuscles may be seen under the microscope.

On examination, in the left lateral fornix was a solid, movable tumour, the size of a chestnut, very sensitive; in the right half was a thickened and sensitive spot, but no movable tumour. In Douglas's pouch was an enlarged Fallopian tube.

An operation was performed on Jan. 20th—ovaries and tubes removed on both sides. On left side, the ovary was loosely adherent to the part surrounding it; on right side, the ovary was much freer. The left ovary contained a false corpus luteum. The right ovary was healthy, but the Fallopian tube was blocked up and distended. The free surface of the appendages was everywhere covered by flakes of organised lymph. There was a good deal of bleeding, and a drainage tube was used, which was removed on the 25th. The case was discharged cured on Feb. 12th. This was evidently a case of chronic ovaritis following gonorrhœa.

Remarks.—The operations were done with strict antiseptic precautions, but without the spray. In the second case the temperature rose on the first and second days to 100·6°, and on the ninth to 102°. With these exceptions, the temperature never rose above 100° in any of the four cases.

ON the 31st ult. a Local Government Board inquiry was held at Highgate respecting an application by the Hornsey Local Board to borrow £7663 for works of sewerage and public improvement. There was some opposition to the scheme, but ultimately the inspector intimated that he should report favourably upon the application.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Acute Cardiac Dilatation from Alcoholism. — Endemic Hæmaturia.—Lupus treated partly by Scraping and partly by Salicylic Paste.—Hammer Toe.

THE last meeting of the session was held on the 27th ult., Dr. W. H. Broadbent, President, in the chair. The report of the committee on Charcot's Joint Disease and of that on Myxœdema have been completed, and will be published in the ensuing session.

Dr. ROBERT MAGUIRE read a paper on Acute Dilatation of the Heart produced by Alcoholism. Alcoholism produces acute changes in the nervous and circulatory systems. The latter are not usually of serious moment, but may occasionally be important, as shown by the two cases here given. The first patient (aged twenty-three), when applying for treatment, showed œdema of the legs and some ascites. The pulse was small, weak, and of low tension, beating at the rate of 140 per minute. The heart beat was diffused, apex outside nipple not lowered, and epigastric pulsation excessive. Cardiac dulness was extended vertically and laterally. The cardiac sounds were short, weak, and spaced, and a slight systolic murmur was heard. There was dyspnœa, but no abnormal pulmonary sounds. The urine was excessive in quantity, and of low specific gravity. There was no history of rheumatism or of previous cardiac symptoms, and, after excluding all other causes, it seemed clear that the dilatation of the heart was produced by alcoholism, of which the patient gave a pronounced history. Under treatment by cardiac tonics the symptoms and the enlargement of the heart entirely disappeared. The second patient, aged forty-three, when first seen, had œdema of the legs, tremor of the tongue and hands, and complained of nervousness and want of sleep. The pulse was small, feeble, and easily compressible. The after-beat of the heart was outside the nipple line, and was somewhat diffused. The transverse dulness of the heart was increased in extent. The cardiac sounds were short and sharp, but no murmurs were to be heard. As in the previous case, no cause could be found for the dilatation of the heart, other than acute alcoholism, of which the history was clear. Under treatment the symptoms entirely disappeared. The mechanism by which alcoholism produces the dilatation is probably not by increasing the peripheric resistance, but by poisoning the heart muscle itself, so causing it to give way before a normal, or even a reduced, arterial tension.—Dr. BROADBENT said the subject of the paper was novel to him, but it was not easy to understand how the dilatation was produced, unless it were aided by the imbibition of large quantities of alcohol without food, thus increasing peripheral resistance.—Dr. ORMEROD asked what form of alcohol had been taken, for Leyden had noted similar conditions to follow beer-drinking.—Dr. STEPHEN MACKENZIE said that he agreed with the view taken by Dr. Maguire, though pyrexia should be borne in mind as a cause of myocardial dilatation; also actual myocarditis may occur under various circumstances.—Dr. EWART said that beer-drinking, though very common, could hardly be the explanation, unless combined with other causes. He had not observed dilatation to commence in the left ventricle, nor considered that it was due to toxic effects. With dilatation of the heart or of any of the cavities he would expect to find an increased (and enfeebled) rate of the heart's action, and this might not correspond to the pulse rate.—Dr. HINGSTON FOX remarked that a single testing for albuminuria would be insufficient to exclude it.—Dr. MAGUIRE, in reply, said gin was the alcohol consumed. The urine had been carefully examined. Also, he had been careful to eliminate any possibility of peripheric resistance being operative in the causation of the dilatation, and even after recovery arterial tension was not in excess.

Dr. HANDFORD communicated a case of Endemic Hæmaturia that he had had under observation for a year and three-quarters. The patient was a fresh-complexioned, healthy-looking man, aged twenty-four. He had gone to Natal at the age of twenty-one, and had remained there for three years and a half. He first passed blood in the urine on the voyage home. While in Natal he enjoyed good health, except for two attacks of dengue. When first seen in

Digitized by Google

November, 1885, he complained of pains in the loins, occasional discomfort in micturition, and the passage of blood in the urine. Numerous ova and embryos of the distomum (bilharzia) hæmatobium were discovered in the urine, and are still to be found, though in much smaller numbers, at the present time (March, 1887). The following were the points of chief clinical interest raised:—1st. Can the parasite multipy within the human body, or is an "intermediate host" necessary? 2nd. In the latter case, and in the absence of reinfection (and the conditions for reinfection are not known to exist in this country), what is the "expedition of life" of the parasites, and may the host reasonably expect to outlive his guests? 3rd. Is any parasiticide treatment useful? 4th. What is the method of infection? What precautions should be recommended with a view to prophylaxis?—Dr. SHARKEY had examined specimens from Cairo, showing ova in the kidneys, lymphatic glands, and even in the skin.—Dr. COUPLAND had observed them in specimens, sent by Dr. Kartuliz, in the lungs.—Dr. HANDFORD said in this country it would be a waste of time to try to discover the (probable) intermediate host.

Dr. DREWITT read a paper on the case of a child in whom a patch of Lupus had been divided for treatment into two parts, of which one part had been treated with salicycle acid and creasote, and the other by scraping. An unusual opportunity was thus offered of comparing the two methods. There had been altogether eight applications of Unna's plaster of salicylic acid and creasote during one month, each application having been preceded by washing the patch with a solution of cocaine. At the end of that time the granulation nodules had all suppurated out, leaving little pits surrounded by unhurt, healthy skin. There had been no return of the disease in either part. Unna claimed for the salicylic acid treatment that it removed old bands. This it had failed to do in this case—in fact, some new, thin bands had been formed; but still the scars left by the salicylic acid were smaller and less hard, and had less tendency to contract, than those left by scraping, and, judging from this case alone, there is distinct evidence in favour of the salicylic acid treatment of lupus. The case was shown with a drawing.

Mr. W. ANDERSON read a paper on a case of Hammer Toe, with some remarks upon the deformity. The patient, a youth aged nineteen, had been suffering from hammer toe, presenting the usual characters, and affecting the second digit of the right foot. The history showed that the condition had been noticed from early infancy, and that an aunt and two cousins on the parental side had been similarly affected. The deformity was treated by removal of the head of the first phalanx, which was exposed by a longitudinal incision through the integuments and extensor tendon. The toe was straightened, and healing took place by first intention. The following points with reference to the disease, as illustrated by an analysis of twenty cases, were then brought forward: 1. The complaint is peculiarly one of early life, the period of commencement, in genuine examples, appearing to range between infancy and the age of twenty-one. 2. The lesion is almost always limited to the first phalangeal joint of the second toe, but occasionally appears on the metatarso-phalangeal joint of the great toe (which developmentally must be regarded as belonging to the interphalangeal series). The cases described as "hallux flexus" by Mr. Davies-Colley a few weeks since are of this nature. 3. True hammer toe is often bilateral, but when this is the case one foot is commonly attacked several years before the other. 4. A history of an inherited tendency to the disease may often be obtained. 5. The development of the complaint does not appear to be affected by either sex or class, or to be connected with any special constitutional diathesis. 6. There is no good reason to believe that it is caused by ill-made boots. There is, of course, no doubt that the distortion is sometimes associated, probably as a mere coincidence, with evidences of the habitual use of misshapen foot covering, but in many cases the normal form of the foot is preserved, and there is no reason to believe that the shoemaker has ever been at fault. 7. The essential pathological lesion is a contraction of the plantar fibres of the lateral ligaments and of the glenoid plate, probably the result of a peculiar form of chronic inflammation. Secondary changes of form occur in the articular surfaces, particularly in the cartilage, and may lead to a trigger-like action of the affected joint during forcible flexion and extension. The muscles, tendons, and fasciæ take no part in the etiology, but may be secondarily affected. 8. The treatment recommended is removal of the head of the first phalanx in the manner described. Two specimens, one lent by Mr. Shattock, and some drawings were shown to illustrate the pathology of the affection.—Mr. W. ADAMS said that a study of the dissections would show that it was the fault of the lateral ligaments. Division of these ligaments should be practised, not amputation, between the ages of twelve and eighteen. Mr. Anderson's suggestion was a very valuable one. The pathology still remained obscure.—Mr. NUNN considered that a defective development of the spinal cord was the cause of the deformity. A case of a lady with a hammer toe had a son who did not develop the condition till thirteen years of age.—Mr. R. W. PARKER had seen many cases in young children, even infants, so that the foot covering was not a cause. It was difficult to see why accidental causes should affect the second toe so frequently. Removal of the toe was his practice.—In reply to Mr. Broadbent, Mr. ANDERSON said that he did not know whether the condition was more common in town or country children.

The following living specimens were shown:—Dr. Arthur Davies: A case of Rhythmical Tremors affecting only the Right Arm. Mr. George Eastes: Chronic Spasmodic Affection of Inspiratory Muscles with Loud Crowing Inspiration. Mr. Bernard Pitts: Congenital Scoliosis with other Malformations. Mr. Battle: Osteotomy for Congenital Talipes. Mr. Black: Double Congenital Dislocation of Hip.

ACADEMY OF MEDICINE IN IRELAND.

Exhibition of Specimens.—Treatment of Vesico-vaginal and Vesico-uterine Fistulæ.

AT a meeting of the Obstetrical Section, held on April 1st, Dr. ALFRED SMITH exhibited an Encephalocele. The interesting point was the enormous size of the child, which was 21 in. long and 11 lb. in weight. This was perhaps because the brain had ceased to require food, and the additional supply went to the other parts of the body. The child had come to its full term.

The PRESIDENT exhibited a Multicular Ovarian Cyst, which was peculiar in consisting of two very large cysts and one smaller one, which were all connected by a common isthmus, so that at the operation he first thought it was a case of double ovarian tumour. A large quantity of the cyst fluid escaped into the abdominal cavity, which was therefore washed out with very weak carbolic acid solution. The woman's urine for some days contained a very large quantity of indican, but she made a typical afebrile convalescence.

The PRESIDENT also exhibited a Malignant Growth which had been removed from the cervix uteri by Schroeder's operation. The patient was a strong, stout, healthy, florid-looking woman, and the only symptom was menorrhagia, which had lasted for eight months. The old method of removal was by putting an écraseur round the base of the tumour. The woman had a perfectly afebrile convalescence.

Dr. MORE MADDEN read a paper on the Treatment of Vesico-vaginal Fistulæ. In the present communication the writer confines himself to those more difficult and exceptional cases of vesical fistula consequent on parturition. Amongst these Dr. More Madden includes all cases of vesico-vaginal or vesico-uterine fistula in which the loss of tissue or the position and character of the rupture are such as to preclude the restoration of the former structural integrity of the parts, and in which either new vesico-vaginal or vesico-uterine walls must be built up by plastic operation, or else a new condition of the parts must be established. In most of the instances of vesico-uterine fistula that have come under Dr. More Madden's observation the patients had been delivered instrumentally, and, moreover, were pluriparæ in whom the uterine walls had been previously softened and disintegrated by imperfect involution. In the latter cases there are, as a rule, but three courses available in the way of operative treatment—viz., tracheloraphy in the first instance, followed by a plastic operation on the disruptured vesico-uterine walls; secondly, closure of the os uteri, so as to convert the uterus into an appendix to the bladder; or, thirdly, the same result may be obtained in some cases by turning the cervix into the vesical wound, within the closed walls of which it may be included. In this connexion Dr. More Madden refers to a case in which, after the

Digitized by Google

normal aperture of the uterus was thus closed, nevertheless the patient subsequently again became pregnant. In some exceptional instances, however, of destruction from sloughing of the entire vesico-vaginal septum, none of the reparative operations usually recommended are feasible or effectual, and in such cases the advisability of closing the vaginal orifice, so as to thus afford a possible restitution of retentive power, becomes a question for consideration. Against Simon's operation for this purpose must be recognised the consequent liability to fatal renal disease which Dr. Emmet holds to be an inevitable result of its performance. Nor should it be lost sight of in this connexion that in some instances the most extensive vesico-vaginal fistulæ may in course of time become cured without any operation by the occurrence of senile atresia of the vagina—a fact of which two cases have come under Dr. More Madden's observation.—Dr. ROE said it was the experience of most of them that in all cases that occurred of vesico-vaginal fistula the deliveries had been effected by instruments. But it would be wrong to let it go forth as the opinion of the Section that the instruments were the cause of these fistulæ. He believed that in the majority of cases the fistulæ were the result of sloughing.—Dr. HORNE said that Dr. Madden, in his paper, had divided fistulæ into two great classes. As regarded the first of these, they were all agreed that where the bands of adhesion were not very great, and the edges of the denuded surfaces could be easily brought together, there could be no hesitation about performing the operation. The great question was whether it should be performed when the loss of tissue at the base of the bladder had been so great that, whether the bands were divided or not, it was not possible to bring the edges of the wound together.—The PRESIDENT said, when they looked back upon the history of vesico-vaginal fistula, it was extremely interesting to find that a disease which at one time was considered almost incurable could now, except in the worst cases, be cured with absolute certainty; and they should never cease to hope that some day even the severer cases should be brought within the power of the gynæcologist. No person in modern times, with the exception of Marion Sims, had done so much to show them how this disease ought to be treated as the late Professor Simon. It was most desirable to draw the attention of young men to the conditions he had laid down as necessary for the cure of these cases. First of all, broad freshened surfaces were required; secondly, all tension should be taken off the edges; lastly, the edges should be brought accurately together by plenty of stitches. Dr. Roe had opened an interesting question as to the etiology of those cases. When he (the President) was first studying them he was under the impression that it was in cases of first childbirth that vesico-vaginal fistula occurred most frequently. But he had not found that most of the cases of the disease that came from the country were cases of first birth; on the contrary, the majority of the women had borne children before; and he thought the occurrence of the disease in them was to be explained by the tediousness of their labours. These considerations point to the fact that it was not great pressure but prolonged pressure that caused vesico-vaginal fistula. Dr. Horne had drawn attention to the circumstances under which stone was likely to form in the bladder. When the bladder was in its normal condition it was emptied from the lowest point, and then its contents could be always cleared out. But in some cases the opening between the bladder and the vagina was high up in the former, and the result was that there was a pocket up to the level of where the fistula was, which was constantly full of unchanged urine. The salts of that urine were then deposited, and stones formed.—Dr. MORE MADDEN replied.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE eighth ordinary meeting was held on May 25th, in the Faculty Hall.

Dr. ROBERT POLLOK exhibited a small Pediculated Polypus which he had removed from the os uteri of a patient who had been supposed to be suffering from prolapsus and had been wearing a pessary, and afterwards read "Notes of Difficulties occurring in eleven years' private Obstetric Practice (2000 cases), with the Treatment adopted." The difficulties alluded to include adherent placenta, funis presentation, anencephalic fœtus, dystocia from obstructing tumour, placenta prævia, post-partum hæmorrhage, puerperal eclampsia, and extra-uterine pregnancy. A discussion followed, in the course of which the diagnosis in the latter case was called in question by Dr. Abraham Wallace, and the author's views as to treatment were freely criticised.

Notices of Books.

The Essentials of Bandaging, with Directions for managing Fractures and Dislocations, for administering Ether and Chloroform, and for using other Surgical Apparatus. With a Chapter on Surgical Landmarks. By BERKELEY HILL, M.B. Lond., F.R.C.S., Professor of Clinical Surgery in University College, Member of the Court of Examiners of the Royal College of Surgeons of England. Illustrated by 144 Engravings on Wood. Sixth Edition, Revised and Enlarged. London: H. K. Lewis. 1887.—This is a deservedly popular book, so much so that a sixth edition has been called for. The whole has been revised, and to some small extent the book is enlarged; but on looking through it we notice some few points in which further improvements could easily have been introduced. The descriptions of bandages and splints are practically unaltered, but we are glad to notice that Mr. Hill gives a caution as to the danger of sloughing following the use of the graduated compress in the treatment of a wound of the palmar arch, and recommends the enlargement of the wound and double ligature of the vessel instead. He might have added that if the bandage affixing the compress is loosened after twenty-four hours without displacement of the compress, the danger of sloughing is obviated. Mr. Tweedy has written a short account of Retinoscopy, and Dr. Poore has added a description of Catheterism of the Larynx. We are surprised that no account of the many convenient uses of the triangular bandage is given; we miss also a description and proper illustrations of the various simple slings for the hand and arm. The old account and woodcuts of reduction of dislocations of the hip by pulleys are still left in, and considering that this mode of reduction is now rarely, if indeed ever, used by an educated surgeon, it would have been more useful to replace these diagrams by others of the modes of reduction by manipulation. A still stranger instance of "survival" under many revises, is the account of the mode of administering a hypodermic injection. We should suppose that there was hardly any room for difference of opinion as to the best way of performing this trifling operation, and that everyone did it by gently pinching up a fold of skin and thrusting in the needle parallel to the surface. But Mr. Hill recommends the surgeon to choose the arm (not the forearm), and to steady the skin "by putting it on the stretch with the left thumb and fingers, while the point of the cannula, held at right angles with the surface, is thrust quickly, with a slight rotatary motion, completely through the skin. We must add one further criticism, and it is in regard to the application of Scott's dressing to a joint. The ointment is called "mercurial ointment," and there is no allusion to the fact that it should be a special preparation of mercury and camphor.

Congenital Club-foot: its Nature and Treatment; with especial reference to the Subcutaneous Division of the Tarsal Ligaments. By ROBERT WILLIAM PARKER, Surgeon to the East London Hospital for Children, and to the Grosvenor Hospital for Women and Children. London: H. K. Lewis. 1887.—Mr. Parker has, in conjunction with his friend and co-worker Mr. Shattock, studied the pathology of club-foot, and the present *brochure* is an amplification and practical application of the paper already published in the Transactions of the Pathological Society. Mr. Parker's views are the outcome of painstaking study of the anatomy of club-foot, and are worthy of the most careful consideration. Put briefly, his teaching is that the cause of congenital

Digitized by Google

club-foot is malposition in utero, preventing the proper developmental changes in the foot; that not only are muscles at fault, but bones and ligaments too; that in severe cases the shortened ligaments offer great and, it may be, insuperable obstacles to the correction of the deformity, and are the cause of the frequent relapses after tenotomy; that tenotomy should be often supplemented or replaced by division of the shortened ligaments—syndesmotomy as it is called. We believe that Mr. Parker has made a valuable addition to our knowledge and our means of surely remedying one of the commonest of deformities. The book is, however, weak on its clinical side. The pathological argument is complete, but not a case is given to show the practical value of the treatment recommended. We are well aware that the loading of *brochures* with accounts of cases is a vulgar device of unscientific writers, but none the less is it to be wished that Mr. Parker had recorded one or two of the cases in which he has practised syndesmotomy. The book is excellent, but it needs a clinical appendix.

Druitt's Surgeon's Vade-Mecum; a Manual of Modern Surgery. Edited by STANLEY BOYD, M.B., B.S. Lond., F.R.C.S. Eng., Assistant-Surgeon and Pathologist to the Charing-cross Hospital, and Surgeon to the Paddington-green Hospital for Children. Twelfth Edition, with 373 Wood Engravings. London: Henry Renshaw; J. and A. Churchill. 1887.—This is an old friend, but in its new form shows none of the decadence of age, but all the vigour of youth. Mr. Stanley Boyd has amply justified the confidence placed in him by the publishers, and we most heartily congratulate him upon the success of this, which, we believe, is his first literary effort of an important kind. Every part of the book shows signs of careful and judicious revision, and while the well-known characteristics of Druitt's book, which have been appreciated by many generations of students, are preserved, all the chapters have been brought well up to date. The most important alteration made in this edition is the incorporation of a good account of antiseptic surgery in all its branches, and of the changes introduced into pathological views by the recent discoveries of the important *rôle* played by micro-organisms in many morbid processes. The arrangement, the illustrations, and the size of the book have been improved, and it is in every way a trustworthy text-book. The twelfth edition ought to do more than maintain the reputation Dr. Druitt earned.

A Treatise on Chemistry. By Sir H. E. ROSCOE, F.R.S., and C. SCHORLEMMER, F.R.S., Professors of Chemistry in the Victoria University, Owens College, Manchester. Vol. III. Part III.: The Chemistry of the Hydro-carbons and their Derivatives, or Organic Chemistry. London: Macmillan and Co. 1886.—This, the third part of the third volume of the great work which the Manchester professors have in hand, is, after all, only another small instalment, and leaves almost any amount to be completed. The present volume "commences the consideration of the complicated but most important series of bodies known as the aromatic compounds"; in fact, it deals with benzene and its simpler derivatives, including, of course, the phenol and aniline. It is quite equal in value to the preceding volumes, which is saying a great deal. The section on benzene itself is a model of scientific writing; it is eminently practical, with good working directions and clear illustrations, and yet the scientific idea is never lost sight of throughout. As in the previous volumes, unusual prominence is given to the history of each important compound. It is not universally recognised that such history is essential for the true comprehension of the present views. We trust there will be as little delay as possible in the issue of the remaining volumes. The book will remain a landmark in the history of English chemistry. It is unnecessary to praise it, for every chemist in England knows and values it.

Brain: a Journal of Neurology. Edited for the Neurological Society of London by A. DE WATTEVILLE. Part 37. April, 1887. London: Macmillan and Co. 1887.—This, which is the first number of *Brain* since it has been converted into the organ of the Neurological Society, is almost wholly occupied with an elaborate paper by Dr. Bastian, read before that Society, upon the Muscular Sense, its Nature and Cortical Localisation. It would be impossible, within the space of a brief notice, to detail the points laid down by Dr. Bastian, whose argument is directed largely against the doctrines enunciated by Dr. Ferrier. The interest of the subject is heightened by the publication of the full text of the discussion which followed upon the reading of the paper, and was joined in by Dr. Ferrier, Mr. Sully, Dr. Ross, Sir J. Crichton Browne, Dr. Hughlings Jackson, Professor Horsley, Professor Haycraft, Dr. Mercier, and Dr. de Watteville, and the reply of Dr. Bastian to the criticisms of these gentlemen. Beyond this subject, the journal contains a Critical Digest on Peripheral Neuritis by Dr. Pierson of Dresden, and an abstract of a paper by Landouzy and Déjérine on Progressive Atrophic Myopathy involving the Face.

The New Sydenham Society's Lexicon of Medicine and the Allied Sciences.—The thirteenth part of this dictionary, which is edited by Henry Power, M.B., and Dr. Leonard W. Sedgwick, has just been issued. It extends from "Her" to "Ilm," and its publication is another step towards the completion of a work that will in the future be of immense value to those who are fortunate enough to possess it.

Pen and Pencil. Glasgow: Maclure, Macdonald, and Co.—Several numbers of this recently established illustrated weekly newspaper have been forwarded to us. Each part contains eight pages, and with several a supplement is also issued, of high class illustrations and interesting letterpress. As a means of implanting and encouraging the love of the beautiful and refined we are glad to afford it a hearty welcome.

ROYAL MEDICAL BENEVOLENT COLLEGE.

AT the annual general meeting of the governors of the Royal Medical Benevolent College at Epsom, held on May 25th, Mr. Hird, who has filled the office of treasurer for many years, resigned in consequence of giving up practice in London. He was unanimously elected a vice-president, and received a most hearty vote of thanks for his services. Dr. Holman, of Reigate, on the recommendation of the council, was elected as the new treasurer. He is well known in the profession, and has been an earnest supporter of the College for a lengthened period.

The aid given by this institution to the aged and helpless by pensions, the education free of all cost afforded to the children of the less prosperous members of the profession, and the really first-rate education given to sons of any medical practitioner for £55 a year, are all so many reasons why every member of the profession should support the College, and yet we are grieved to say not one-fifth of our number give anything. It is not, perhaps, sufficiently known that the College has several good scholarships to the universities. It has seven free medical scholarships to the metropolitan hospitals, besides numerous other minor exhibitions. With Dr. Jonson, Sir Edward Sieveking, Mr. France, Sir Joseph Fayrer, Sir Trevor Lawrence, M.P., Mr. Morrant Baker, Mr. Page, Mr. Malcolm Morris, Dr. Frederick Taylor, and Mr. Propert, the son of the founder, on the Council, we cannot but hope that the new treasurer and his colleagues may receive a generous pecuniary support to enable them to carry on the charitable objects of the institution with no niggard hand, and, at the same time, to be shown such confidence by sending pupils there as may secure a triumphant success for their efforts to place Epsom College in the front rank of the schools of the country.

THE LANCET.

LONDON: SATURDAY, JUNE 4, 1887.

THE lecture delivered by Dr. KLEIN last week at the Royal Institution placed before the public the complete evidence upon which is based the opinion that the infection of milk with the virus of scarlet fever may result from a disease of the cow. Although the papers which have from time to time appeared in the reports of the Medical Officer of the Local Government Board have indicated the insufficiency of the more commonly accepted methods of milk infection to account for this infection, and although, therefore, it was seen that some condition of the cow herself might be responsible for this occurrence, it was not until the publication of Mr. POWER'S investigation into scarlet fever caused by milk coming from a farm at Hendon that evidence was obtained that the disease was due to a particular affection of this animal.

It will be recollected that the appearance of scarlet fever among the drinkers of milk from one and another shed on this farm coincided with extraordinary exactness with the appearance of a disease among the cows inhabiting these sheds, and that further proof that the cow and the human disease were related was afforded by Dr. KLEIN, who discovered in certain sores on the udders of the affected cows a streptococcus which, when inoculated into calves, caused the same disease as that from which the cows at Hendon suffered; and that, further, the changes in the viscera of these animals resembled those which are found in the human subject after death from scarlet fever, and that the same micrococcus was discovered in their blood and tissues as was found in the Hendon cows.

Since this time an outbreak of scarlet fever at Wimbledon, again due to milk, gave opportunity for Dr. KLEIN to extend his inquiry. A monkey, one of the milk drinkers and a sufferer from its infective properties, had died, and an examination of its body by Dr. KLEIN left no doubt that the cause of death was scarlet fever. From the blood of this monkey he obtained by cultivation the same micrococcus as that found in the Hendon cows. Again, some tins of condensed milk which were under suspicion of having produced scarlet fever in a number of persons who had partaken of it were forwarded to Dr. KLEIN, with the result that among other organisms the same micrococcus was distinguished. The action of this microbe was tested on animals, and communicated to them the same disease as that observed at Hendon. Dr. KLEIN finally directed his attention to persons suffering from scarlet fever, and discovered in the blood of the general circulation a species of micrococcus which, on cultivation in nutritive gelatine, agar-agar mixture, blood-serum, and other media, proved to be in every respect identical with that obtained from the Hendon cows.

The identity of the human and the animal organisms having been thus far established, both were tested on animals and the results compared. Mice, especially wild mice, when inoculated or fed with the streptococcus, both animal and human became affected exactly in the same manner. The majority of them died between seven and twenty days afterwards, the post-mortem examination revealing great congestion of the lungs and congestion of the liver, spleen, and cortical part of the kidney. From the blood of these animals, taken directly from the heart, cultivations were made, and the existence of the same micrococcus proved. For the remaining experiments calves were employed. Four being fed and four being inoculated with cultivations from cases of human scarlatina, all eight animals developed the disease, both cutaneous and visceral, identical with that produced in the calves that had been infected last year with the micrococcus from the Hendon cows. And, lastly, from the blood taken from the heart of calves thus inoculated with human scarlatina, was recovered by cultivation a micrococcus possessing all the characters of that of the Hendon cows and of the cases of human scarlatina.

The evidence is therefore complete, and we may accept as an assured fact that the conclusions to which Mr. POWER'S investigations of last year pointed were absolutely correct. It is impossible to exaggerate the importance of these observations, both in the saving of human life which they will ultimately effect, and in the security they will give to the interests of agriculturists when further knowledge of the bovine disease enables it to be more easily recognised, and its nature to be better understood. Unfortunately it may yet be some time before the practical lessons which are taught by Mr. POWER'S and Dr. KLEIN'S work are turned to useful account.

While Dr. KLEIN has been thus engaged in the completion of this chain of evidence, another department of the State, the Agricultural Department of the Privy Council Office, has been employed in the production of a document which will excite considerable surprise. The Privy Council had ordered an inquiry into the subject matter of Mr. POWER'S report, but the investigation proved abortive, for we learn from a letter addressed to the Privy Council by Professor BROWN that, owing to the alarm which was occasioned among dairy farmers by the publication of the report of the Local Government Board, it was found impossible to obtain any information from them of the existence of the disease among their herds. Nevertheless, the department appears to have felt the necessity of publishing a report, and they have therefore issued one by Professor AXE, who inspected the Hendon cows at the instigation of the British Dairy Farmers' Association, but arrived upon the scene at a time when, to use his own words, "the eruption on the teats and udder, which was the characteristic feature of the complaint, had in the majority of cases altogether disappeared." Professor AXE has therefore based his description of the malady also upon "information obtained from the farmer and his herdsmen, as well as from other dairymen to whose herd the disease spread." It is obvious from this statement that Professor AXE has from the beginning assumed that the malady of the Hendon cows was identical with that of other herds, which, he states, without giving his source of information, had been associated with those introducing the scarlatinal disease upon the farm; these other herds do not appear to have been seen by Professor AXE at the time of their illness, and the description must be, therefore, based upon his own

Digitized by Google

limited experience of the Hendon malady, and upon the observations of dairymen of the ailment or ailments of other herds, which may have been suffering from one or more of the vesicular diseases which attack the udder of the bovine animal, and which are perhaps affections totally different from that with which Mr. POWER was concerned. Subsequently Professor AXE proceeded to ascertain whether the milk of these other herds had communicated scarlet fever to the drinkers of their milk; and, failing to find evidence of this occurrence, he appears to have concluded that the malady of the Hendon animals was not responsible for the scarlet fever which Mr. POWER investigated.

So serious a conclusion needs to be supported by evidence which will enable some opinion to be formed of its accuracy, but, strangely enough, although adopted by a department of the State, no opportunity is given for such judgment to be arrived at. In the first instance, it is most important to know how far we may trust the observation of the dairymen upon whom Professor AXE relies for information as to these other herds, and we are not even told when inquiry was made of them, and, therefore, whether dependence is being placed upon the memory of these people long after the event. In the second instance, no information is given which would enable anyone to judge of the sufficiency of the inquiry as to the effects of drinking the milk of these herds, nor even is the statement advanced as to the period when inquiry into this branch of the subject was made. There is, indeed, much reason for believing that these steps were not taken until more than a year after the termination of the Hendon outbreak, when all clue would likely enough be lost, and, if so, the publication of this paper sadly needs justification.

Since the publication of Dr. BUCHANAN'S official report and Dr. KLEIN'S lecture at the Royal Institution, the subject is, so far as its scientific position is concerned, outside the region of controversy. The evidence conclusively establishes that the cow malady caused human scarlatina.

THE Anti-vivisection Society of London is still so far alive as to have its May meeting, which was held last week; but it would seem from the report of the proceedings that there is not much animation about it. The chief object of the speakers seemed to be to convince themselves and their audience that the great majority of medical men are against this practice. If by this is meant that the sentiment of humanity in the medical profession is strong, and is painfully touched by the necessity for experiments on animals, we readily admit and accept so just a compliment. We have never erred from the line of a regretful admission of the necessity for, and the undoubted value of, experiments on animals, with a strong request that as far as possible they should be rendered painless. The late Editor of this Journal was known for his love of animals, and his intolerance of anything but kindness to and consideration for them; and in this, as in so much else, he represented accurately the profession. In this sense, then, we will allow that the medical profession feels strongly on the subject of vivisection, but only in this sense. To represent the profession as longing for an overwhelming expression of public opinion—to say as Mr. HAWEIS did, that it is difficult to get at the real opinions of medical men, or, as Dr. HAUGHTON did, that doctors, even of the highest eminence, are afraid to express views which happen to be in opposition to those of the medical profession, is to make statements which are inaccurate, and which refute each other. The medical profession is a liberal profession; it is bound by no creed; it swears by no master; it is confronted daily and nightly with enormous suffering, which enters neither into the imagination nor the experience of ordinary men. Not only has it to face this suffering, but it is expected to mitigate, if not to abolish it. It is this which makes the medical man tolerant of what is called vivisection, which in his hands is a merciful business. What is it that permits men to abuse vaccination so glibly, and clamour for its abolition? Chiefly the fact that by the very beneficence of the operation they disparage they never see small-pox. Experience of this terrible disease would send the race of anti-vaccinators to the nearest vaccination station. So with anti-vivisectionists, they do not see disease, and are not responsible for its treatment. But medical men are. They know, moreover, the solidarity of men and animals in the matter of disease, and that their pathology is so far common that discoveries which benefit men will also, in most cases, benefit the lower animals. These animals, indeed, so far have been large gainers by the discoveries made with the help of experiments on animals, as in the case of anthrax. To read the speeches and the books of anti-vivisectionists, one would think that animals had no diseases, and no interest in the progress of the art of medicine. No assertion could be more at variance with truth, or even with the Scripture which tells us that the "whole Creation groaneth and travaileth in pain." Let the enormous mass of disease in animals be realised, and it will appear but fair to them, as well as to men, to make them parties to those great discoveries by which disease is to be averted. We will not depart from that studied moderation of language which has characterised British men of science in urging for the right to perform careful and, wherever possible, painless experiments on animals, with a view to a deeper knowledge of life and of the things that destroy it and save it respectively. We confess to finding it hard sometimes to preserve this moderation and to be perfectly cool with an opponent who may be willing to shoot an animal and thereafter to eat it, but who objects to the physiologist or the physician performing an operation that may save herds of animals and thousands of human beings. But moderation has its reward, and in regard to this very subject has had its reward already. We may respect the motives of men who object to an experiment on a dog even if it is to save the life of a man, but we cannot admit their sense of proportion or their intelligent interpretation of Holy Writ, which very clearly indicates the different value of the life of man as compared with that of animals.

SINCE the true nature of the tubercular virus was revealed by KOCH, there has been a constant endeavour to bring the accepted facts of clinical observation into harmony with that discovery. The range of tuberculous disease has been widely extended, and especial prominence given to that form which in its abundance far exceeds all others—we

Digitized by Google

mean pulmonary phthisis. According to the knowledge gained of the invariable coincidence of the bacillus of tubercle and of phthisis, we are bound to include the lung affection in the same pathological category as that of other tubercular disease in any part of the body. When, therefore, we speak of the etiology of phthisis, we mean the etiology of tuberculosis; and when we indicate the fact of inheritance as one of the most striking of the etiological factors in phthisis, we must add the liability to the transmission of any one of the several forms of tubercular disease. This is so obvious that it barely needs to be pointed out, and yet we venture to think that it is sometimes lost sight of. It is not the pulmonary disease that is inherited, but the tuberculosis, of which the pulmonary affection is but one manifestation; and the fact that we habitually speak of "inherited *phthisis*" is merely because that is the most common of all tubercular disease. If, therefore, we seek to discuss the influence which the bacillary doctrine has had upon the problem of the inheritance of phthisis, we must embrace in our view the whole range of tubercular disease. The question, then, is whether tuberculosis, like syphilis, can be directly transmitted from parent to offspring; and if the answer is in the negative, we must be prepared with a satisfactory alternative to explain the undoubted influence of heredity in the etiology of the disease.

The subject is surrounded by difficulties, and we can hardly wonder that the medical world is divided in opinion upon it. Professor ORTH has recently drawn prominent attention to it,[1] but current literature abounds with references to it. It is simple and easy to evade the question by implying, as VIRCHOW did thirty years ago, that it is not tuberculosis that is transmitted, but only a special vulnerability of tissue or organ; and this explanation may probably be the true one, unsatisfactory as in some respects it is. Still, before accepting it we are bound to see how far it can be supported by facts, and how far it harmonises with the central fact of all—viz., the organised virus, the bacillus. The analogy with syphilis, in many particulars so striking, is hardly borne out in this question of inheritance. That the parent imparts the syphilitic virus to his or her offspring, either directly from the germ or sperm cell or through the medium of the placental blood, is absolutely proved by the existence of congenital and fœtal syphilis. Now, in tuberculosis there is hardly a single well-authenticated case on record of the disease being present in the fœtus or the new-born. The one or two instances of fœtal tuberculosis are not beyond suspicion of being examples of syphilis with widespread visceral lesions, and perhaps the only indubitable case is that of a calf which JOHNE records. But even if there were more cases to be substantiated, it is plain that, as compared with syphilis, they would form but an infinitesimal proportion in the whole number of cases of inherited tuberculosis; and the possibility of accidental infection *in utero* would be quite a legitimate explanation for such a rare occurrence. At any rate, it would be more legitimate than the endeavour to clench the analogy with syphilis by assuming that inherited tuberculosis is always latent, and that what is the exception in the former disease is the rule in the latter. The positive arguments in favour of direct transmission are mainly based upon such facts as those adduced by LANDOUZY—viz., the detection of bacilli in the vesiculæ seminales of tubercular subjects, without actual disease of those organs, and the experimental inoculation of tuberculosis in guinea-pigs by the injection of the spermatic fluid from a tubercular subject. In face of the transmission of syphilis, it cannot be contended that it is impossible for the sperm cell or germ cell to be primarily infected; but the proof of such infection is wanting in the case of tuberculosis, or is at least so meagre as to be unimportant. In his very suggestive work just published, Mr. CANDLER,[2] who adopts the malarial doctrine of tuberculosis, says: "In syphilis the microbe is in the blood from the beginning to the end of its parasitism, in phthisis the irruption of the bacillus into the blood is the first scene of the last short act in its career as a parasite in the one host. Hereditary syphilis therefore, in addition to its being clearly established, may be readily apprehended, but hereditary phthisis in the sense implied would appear to be a physical impossibility."

Nevertheless, in spite of the absence of evidence of congenital tuberculosis, and the fact that inherited phthisis delays its appearance mostly till puberty has been passed, the occurrence of infantile tuberculosis is by no means so rare as is generally believed. In a paper read at the Copenhagen Congress, Dr. HELLER showed that whereas out of a total of 1300 post-mortem examinations in infants and children he had met with only one case of tubercular disease as early as nine weeks of age, yet the proportion increased with considerable rapidity as the age advanced, even in the first years of life; and M. LANDOUZY has contributed from his recent experience at the Tenon Hospital, Paris, details of no fewer than seven fatal cases of tuberculosis in infants ranging from six weeks to twelve months, among twenty-three cases of death during the first quarter of this year.[3] It may be admitted that infantile tuberculosis is common (although infantile phthisis is exceedingly rare) without necessarily concluding that the disease has been directly inherited—that is, that it is congenital. There is always a possibility of post-uterine infection by the milk of a tubercular mother or by exposure to the vitiated surroundings of a home inhabited by infected parents. It is more reasonable to admit acquired disease than to assume that during fœtal life and for a few weeks subsequently the disease remained dormant. From these and other considerations, we are almost impelled by the bacillary doctrine to believe that the old assumption is the true one—viz., that inheritance of phthisis (and of tuberculosis in its widest sense) is not an inheritance of the disease itself, but of a special proclivity of tissue to the disease. It is the soil that is suitable for the growth of the bacillus, and not the bacillus, that is transmitted. As KOCH says, "hereditary tuberculosis is explained most naturally by supposing that the infective germ itself is not inherited, but rather certain peculiarities favourable to the development of germs which may later on come into contact with the body; in fact, it is the predisposition to tuberculosis which is inherited." The same conclusion is reached by Professor ORTH, and it

is the one which is most in consonance with experience; but, as Professor ORTH remarks, it by no means gets rid of the fact that the disease is infective.

IN our last issue we referred briefly to the recommendations of the Practical Education Committee of the General Medical Council on the question of pupilage, and pointed out how inadequate was the suggestion of a six months' pupilage taken in the long vacations after the passing of the examinations in anatomy and physiology. We regret that the part of the report which deals with the final examinations is equally unsatisfactory. Its recommendations are unworkable. It is suggested that the extension and searching power of the clinical examinations would be facilitated "if the 'final' or qualifying examination were divided into two parts, of which the ultimate should consist mainly of clinical work and the personal application of diagnosis, prognosis, and treatment to set cases, leaving to the penultimate the testing of the knowledge possessed by the candidate of the other subjects contained in the curriculum of school work. It is also recommended that there should be an interval of at least twelve months between the two parts of the final examination, and that this interval should be passed in such occupations as will involve the charge of patients under the supervision of competent persons recognised by the authorities of the school at which the candidate has been educated, which authorities should be responsible for the genuineness of the evidence afforded of the candidate's diligence and care of such number of cases in medicine, surgery, and midwifery as the examining body shall deem expedient." We have every sympathy with attempts to make the qualifying examinations as thoroughly practical in medicine, surgery, and midwifery as is possible, and should have welcomed and supported any proposals which would have really secured this object, or even tended towards this end. For example, the committee might have pointed out that those examining bodies which only require a certificate of attendance on *six* cases of labour were doing very little to secure an efficient practical knowledge of obstetrics, and this is the less pardonable because everyone must recognise the impossibility of a really practical examination in this branch of the medical art. In Ireland the regulations of the examining boards on this question are more stringent than in England, where attendance on twenty cases at least is insisted on by all the present authorities; but in Scotland only six cases are required by any qualifying body, whether University or Faculty. Practical midwifery is at a minimum; theoretical midwifery has to be cultivated to its highest point of excellence by the unfortunate pupil. "Two courses of midwifery of fifty lectures each are reckoned equivalent to one course of one hundred lectures, provided they embrace different departments of obstetric medicine." Again, it would have been worthy of consideration whether operations on the dead subject should not be made compulsory in every surgical examination, as well as the application of bandages and the marking out of the surgical landmarks on the living body. In medicine, should not every candidate be compelled to go through a strict examination both at the bedside and in the out-patient room, and thus have his knowledge tested both of severe and common cases of disease? And could not his therapeutical knowledge be readily and thoroughly examined into at the same time? By such suggestions the practical element in medical education would quickly be increased, for every student is keen enough on learning what he knows will be required of him by the examiner. But the recommendation of a twelve months' interval between two parts of a final examination is quite outside the practicable. There is now a compulsory two years' interval between the second and the qualifying examination at the Conjoint Board, and this interval would, by the adoption of the recommendation referred to, be extended to three years between passing the second examination and obtaining a licence to practise; for if the penultimate part of the examination into the theoretical knowledge embraced in the later part of the curriculum is of any value whatever, it cannot take place until after the present interval of two years. Theoretical surgery and medicine, midwifery, forensic medicine, and pathology, to say nothing of hygiene and mental diseases, cannot be studied under two years, and adding another year compulsorily to the curriculum is impossible, both on the score of time and expense. Another year devoted to medical study is the most valuable boon that can be given by the parent to his son, but his examinations must be finished for him to obtain the greatest benefit from it. His time can then be wholly devoted to the practical element, and he can follow with every advantage the special departments of his hospital, where he can see any number of common diseases, whether of the eye, ear, throat, or skin, gynæcological or exanthematous, and quickly become skilled in their diagnosis and treatment. A year spent thus might not be less profitably employed than in the charge of patients under the supervision of competent persons recognised by the authorities of the school at which the candidate has been educated. Moreover, how could the authorities of a school guarantee the thoroughness of any supervision exercised by practitioners outside their own body? We cannot hope that any improvement in the practical element of medical education will be the outcome of this report, and we are sorry that the committee did not more fully consider the questions involved before they drew it up and allowed it to be entered on the Minutes of the Council.

Annotations.

"Ne quid nimis."

THE SUPPLEMENTARY CHARTER.

ELSEWHERE we publish an abstract of the petition of the Royal College of Surgeons to the Queen for a Supplementary Charter. We have practically discussed all the points contained in it so often that it is needless to do so again on the present occasion. We cannot refrain, however, from pointing out a feature which appears to have been recently introduced by the Council apparently for the purpose of keeping control to some extent over the election of the Council. In the last clause it will be noticed that the Council desire to obtain the power to compel a certain number of Fellows to be present *in propriâ personâ* in order to legalise the election by voting papers, this number of Fellows to be such "as the Council may from time to time think fit to direct." It is clear that, if election by voting

Digitized by Google

paper is to be legalised by Charter, it should be unconditional of any such absurd regulation as the Council appear anxious to introduce. Such a restriction can serve no useful purpose; if it do serve some special purpose, not obvious to outsiders, then the number of Fellows who are to attend personally should be fixed by Charter, and ought not to be allowed to depend on the pleasure of a body like the present Council, who have so persistently ignored all the representations which have been made to them from time to time by the body corporate. There is one other point we may briefly allude to—viz., the proposal to empower the Council to elect annually to the Fellowship ten Members instead of two, as under existing rules. Unless a very different class of men are to be elected to the Fellowship from those originally contemplated, this rule will be useless; for the Council have, so far, not always availed themselves of their present power of electing two Members to the highest grade. We view with disfavour any plan which, on the one hand, tends to depreciate the intrinsic value of the Fellowship, or which gives the Council the means of bestowing, at all largely, a qualification which should be reserved strictly for those who have rendered special service to surgery in one way or another. For the latter purpose, the powers already possessed by the Council seem quite adequate. It would be a waste of time, under present circumstances, to discuss at greater length the abstract in question. We must wait the course of events, and trust to the outspoken wishes of the Fellows and Members, and to their respective deputations which are to wait upon the Lord President of the Council for the purpose of laying them properly before him.

UNIVERSITY COLLEGE AND A TEACHING UNIVERSITY FOR LONDON.

THE arguments which we have so frequently put before our readers as to the advantages which would be obtained by medical students if a Teaching University were founded in London, were well summarised in the speech made by Sir George Young at the distribution of prizes at University College on the 1st instant. The inefficient character of the changes suggested by the Senate of the University of London, and the necessity for the establishment of a local University in London as well as an Imperial Examining Board, were ably pointed out. It is obvious that the movement for establishing a Teaching University in London will go on, and that University and King's Colleges must take the chief, if not the entire, responsibility for forming the Faculties of Arts and Science, and the other medical schools must combine with these to form a Faculty in Medicine. Such changes cannot be foreshadowed without exciting the jealousy of the University of London, which can hardly be expected to look with equanimity on the secession of its two largest and oldest London Colleges so soon after that of Owens College. It is therefore not a matter of surprise that several members of the Council of University College, closely identified with the existing University, have followed the example of Lord Kimberley, the President, and resigned their seats on the Council.

METROPOLITAN ASYLUMS BOARD.

AN interesting report by the Chairman of the Metropolitan Asylums Board has been published, giving an account of the work performed during the fifteen months ending March 25th of the present year. Mr. Galsworthy is able to congratulate the managers on the comparative absence of small-pox from London, and properly claims that some portion of this freedom from disease is due to the existence of opportunities for the isolation of infectious persons. He comments upon the endeavours of the managers to acquire the legal recognition of the position which it has involuntarily assumed in providing hospital accommodation for all classes of the population. Deputations to successive presidents of the Local Government Board on this subject have, he says, only resulted in the adoption of incomplete measures, in consequence of which the Metropolitan Asylums Board has been called upon to do the work of vestries and district boards, but without any legal recognition of responsibility. The proposal that the sanitary authorities should enter into contracts with the Asylums Board for the purpose of the treatment of all classes of the infectious sick has led to no other result than the passing of the Act of 1879 giving permission for this purpose—a permission which, it is needless to say, has not been acted upon. This class distinction between those who are paupers and those who are not leaves London in an unfortunate position with regard to the provision of hospital accommodation; Mr. Galsworthy's suggestion, therefore, that the Local Government Board should introduce a Bill into Parliament with a view to putting an end to these difficulties is one which should receive general support. Among the important arrangements made by the managers during the past twelve months in connexion with the treatment of infectious disease are the adoption of a regulation whereby the services of medical superintendents and assistant medical officers appointed to any infectious hospital will be available for any other hospital of the managers, and the appointment at the hospitals of duly qualified medical men to act as clinical assistants. The first is obviously needed in the interests of the public service, for without such power of transference of officers the managers are compelled to retain a staff at institutions which are for months absolutely empty; the second is necessary to enable medical men to study more thoroughly the diseases which are to be found in the hospitals of the Metropolitan Asylums Board. We note with pleasure that a committee has been appointed by the Board for the purpose of increasing the value of the statistical information which is obtained from every institution. Small-pox and vaccination statistics specially need to be carefully recorded, and an improvement of the methods adopted will lead to valuable results.

ABSENCE OF FREE HYDROCHLORIC ACID IN THE GASTRIC JUICE.

THE diagnostic value of the absence of free hydrochloric acid in the gastric juice in cases of malignant disease of the stomach is discussed at some length in a recent paper by Dr. V. G. Nechaieff of St. Petersburg. For the detection of free hydrochloric acid no less than thirteen different tests have been proposed. Of these he considers the following to be the most useful:—1. A solution of tropeolin in water, as proposed by Edinger; this has of itself a yellow colour, but when brought into contact with a solution containing 0·01 per cent. of HCl it becomes a dark cherry red 2. Methyl violet becomes blue on the addition of 0·025 per cent. of HCl. 3. Congo paper shows a blue tinge on being immersed in a solution containing 0·025 per cent. of HCl. 4. A mixture of three drops of liquor ferri perchloridi with the same quantity of carbolic acid in twenty cubic centimetres of water shows the presence of lactic acid or its salts by becoming yellow; but if free hydrochloric acid is also present the reagent becomes colourless. This is therefore an excellent test for free hydrochloric acid, when lactic acid or the lactates are present. Dr. Nechaieff advises that all these tests should be applied in each case. He found that in cases of carcinoma of the stomach, and apparently in carcinoma of the œsophagus, absence of free hydrochloric acid constituted the rule and its presence the exception, and is disposed, therefore, to think that its absence affords a practically useful diagnostic sign in cases where cancer of the stomach or œsophagus is suspected. Thus, in seven cases of carcinoma of the pylorus, though 142 exami-

Digitized by Google

nations were made, free hydrochloric acid was never found, though lactic acid invariably existed; and, again, in 105 examinations of four patients with carcinomatous stricture of the œsophagus no free hydrochloric acid could be detected. In a case of cancer of the rectum, however, the presence of free hydrochloric acid in the contents of the stomach was very distinct.

CERTIFICATES OF DEATH.

IN a recent annotation respecting the Toxteth-park poisoning case, it was suggested that all cases in which, from the sudden character of the death or other suspicious circumstances, the medical attendant had a doubt as to its being a death from natural causes, should be referred by him to the coroner of the district. No doubt a difficulty is created by the wording of the 20th section of the Births and Deaths Registration Act of 1874, which is as follows:—

"In the case of the death of any person attended during his last illness by a registered medical practitioner, that practitioner shall sign and give to some person required by the Act to give information concerning the death a certificate, stating, to the best of his knowledge and belief, the cause of death."

A correspondent wishing to know whether he or any other medical practitioner could refuse to give a certificate, communicated with the Registrar-General, from whom he received, through the secretary, a reply of which the following is an abstract. After quoting the section of the Act just given, the letter adds:—

"The duty of the medical practitioner is thus very clearly explained by the 20th section of the Act, which admits of no other interpretation..... The medical practitioner under the circumstances described in the Act has no option in the matter; he cannot withold the certificate. He can of course, if he sees fit, himself communicate with the coroner or police with regard to any suspicious circumstances which may have come under his notice when in attendance during the last illness of the deceased; but he may safely leave this duty to the registrar, who in his 'Regulations' is directed to report to the coroner (on a form provided from this office) all deaths caused directly or indirectly by violence, or which have been attended by suspicious circumstances, as well as sudden deaths, and every death the cause of which is stated to be unknown."

It is unfortunate that the Act takes no cognisance of those cases in which it is very difficult, if not impossible, to give a certificate, and in which it would be, medically speaking, much better not to give one. For instance, a practitioner might be in doubt as to whether the cause of death were due to "English cholera" or "irritant poisoning." How is the certificate to be so worded as to induce the registrar to refer the case to the coroner without prejudice to the medical attendant should his suspicions be unfounded? We are by no means so assured as the Registrar-General would appear to be of the safety of leaving this discretionary power to the district registrar. Coroners have frequently complained, and with too much reason, of the delay which often occurs before they receive information of a death in which an inquest has to be held. This delay must be increased, if not caused, by presenting for registration a certificate useless for that purpose, and which must be referred to the coroner—more especially if these officials reside in country districts far from each other. The question is not without its difficulties, but these will be more easily surmounted by meeting them at once, and not shifting them on to the shoulders of others. It will surprise many readers of THE LANCET to learn that they cannot refuse to give a certificate of death, even when such can only be a merely formal one to be passed on by the registrar to the coroner. The obviously better course would be for the medical attendant himself to refer to the coroner every case in which he had doubts as to the propriety of giving a certificate—not necessarily because an inquest was called for, but because the coroner is the authority to whom all such cases ought to be referred, and who is the official responsible for making full inquiry and for the results thereof.

THE GENERAL MEDICAL COUNCIL.

IMMEDIATELY after the termination of the session of the General Medical Council, the printed Minutes of the Council, of its Executive Committee, and of its English Branch Council, including the Transactions from Feb. 25th to May 20th, were published. The volume contains information of the greatest value to the profession and to those interested in its government. In it will be found, in addition to the President's address, all the communications which have taken place concerning the appointment by the Council of assistant examiners to the Apothecaries' Societies of London and Ireland; also a statement of a case and opinion by the Attorney-General and the Solicitor-General in regard to the combination of licensing bodies under the new Medical Act, as well as the proceedings relating to the appointment of inspectors of examinations. Among other documents of interest is the report by a committee on practical education, to which we referred at length in our last number. The early appearance of this volume, with an excellent index, will be appreciated by those interested in medical education.

OXYGEN AS AN ANTIPYRETIC.

AT the last session of the Royal Academy of Medicine of Madrid, the President introduced an innovation by allowing Señor Don Dr. Francisco Valenzuela, a non-member, to read a paper. The subject was "The Effect of Oxygen of High Tension upon the Animal Organism," and the amount of original investigation reported in it may well serve to justify the President of the Academy in departing from the time-honoured custom of confining the papers and speeches to academicians. Don Valenzuela began his researches by submitting rabbits to pure oxygen at various pressures. No effect on the temperature was produced at a lower pressure than 760 mm., or five times the ordinary tension of the oxygen in the atmosphere. Under this, however, a rabbit whose initial temperature was 38·7° C. after an hour's sojourn in the chamber presented a temperature of 37·9° C. At still higher pressures of pure oxygen greater falls of temperature occurred. The highest tension at which experiments were made was 1520 mm.; this reduced a rabbit's temperature in an hour from 38·4° to 32·2°. The general effect on the animals of oxygen at the higher tensions was to produce a temporary torpor, and they came out of the chamber covered with moisture; in a very short time, however, they entirely recovered their ordinary condition. Some experiments were also made on the effect of oxygen of high tension on the febrile state, by inducing septicæmia in rabbits and comparing the course of the disease in those which were subjected to the action of oxygen with that in others kept under ordinary atmospheric conditions, with the general result that pyrexia appeared to be reduced by the sojourn in the oxygen chamber. In one case two rabbits were each inoculated with a cubic centimetre of serous fluid with a putrid smell from a dead body. One of them was then subjected for two hours to the action of oxygen of a tension seven times higher than that which it has in the air. Four hours subsequently the temperature showed a reduction of 1·7° C., the temperature of the other rabbit at the same time being 3° C. higher than the normal. The next day the body heat of the first rabbit was 1·5° C. and the second 3·1 C. above the normal. The first was replaced in the oxygen chamber under the same pressure, and for the same length of time as before,

Digitized by Google

which reduced the temperature 2·2°—that is to say, to 0·7° below the normal. On the third day it was only 1° C. above the normal, while the second rabbit died. No further treatment was resorted to, and on the fourth day the first rabbit had regained its normal physiological condition. It was found in the various experiments made that when a small quantity of septic matter only was introduced, a single session in the oxygen chamber was sufficient to destroy the effect of the virus, but that if a high degree of sepsis was induced the poison was only partially destroyed by a single session. Dr. Valenzuela then made some observations on patients. A young man was attacked by pneumonia, affecting both lungs, on April 26th. On the morning of the 27th the temperature was 39·5° C., and in the evening 40·4°. He was then put into the pneumatic chamber containing pure oxygen at a pressure of 950 mm., or six times the ordinary tension of atmospheric oxygen, for an hour, after which his temperature was 1·7° C. lower. The next morning it was 39·2°. A second session in the chamber produced no immediate reduction, but four hours later the temperature was 39·0°. That evening it was 39·5°, and it gradually returned to normal, though no further sessions in the oxygen chamber were ordered. The man made a rapid recovery. Dr. Valenzuela likewise mentioned some other cases of pneumonia and tuberculosis on which the oxygen treatment appeared to have a beneficial action.

THE CROWN PRINCE OF GERMANY.

WE are glad to be able to give in fuller detail this week an account of the Crown Prince's illness. It appears that in January his Imperial Highness began to suffer from slight hoarseness, and early in March Professor Gerhardt discovered a warty growth attached to the left vocal cord, which he treated by touching with the electro-cautery. Its size having been reduced by this means, the Prince was advised to go to Ems, where he remained about six weeks. On his return he was found to be no better as regards his hoarseness, and the growth had somewhat increased in size. Professor Tobold was then called in, and after a consultation with the Emperor's and Crown Prince's physicians, Von Lauer and Wegner, it was thought that the growth was of a malignant nature, and at their request Dr. Bergmann's opinion was sought. He was inclined to confirm the diagnosis. It was decided that an external operation was necessary, but whether it was to be excision of the larynx or thyrotomy was not settled definitely. In consequence of the strong feeling at Court that this operation ought not to be done unless absolutely unavoidable, on account of its attendant danger to life and great impairment of voice, even if successful, Dr. Bergmann declined to take the responsibility as the operator, unless the impossibility of the removal of the growth by inter-laryngeal methods was confirmed by Dr. Morell Mackenzie. Immediately on arriving in Berlin on Friday, May 20th, a consultation was held, at which Dr. Mackenzie met all the medical men above mentioned. On making a laryngoscopic examination, Dr. Mackenzie found a sessile growth about the size of a large split pea, but in shape more elongated, attached to the posterior portion of the left vocal cord on its inner and upper surfaces. He urged that the more serious operation should not be performed before a portion of the growth had been removed for microscopic examination. This had not been done because it was considered impossible owing to its small size and sessile character. The following morning another consultation was held, at which Dr. Mackenzie succeeded in removing with forceps a piece of the growth about the size of a tare. Professor von Virchow, having examined microscopically the portion taken away, pronounced it to be a benign growth. He said that the epithelial cells were increased in size and number. He further stated that, as the portion removed included a complete section of the growth and the surface of the vocal cord beneath, as clearly demonstrated by the presence of some of the longitudinal elastic fibres of the latter structure, he considered that there was no reason to suppose that any remaining portion of the growth was of a cancerous nature. Professor von Virchow also said that he thought the thickening was the result of chronic inflammation, which accorded with the history of the case. Dr. Mackenzie leaves London for Berlin on Sunday night, and we shall hope to hear that he has been successful in removing the entire growth, which is the source of so much trouble to his Imperial Highness and of so much anxiety to others.

TERRIER'S NEPHRECTOMY.

THE last word has not yet been said upon the relative advantages of the lumbar and the abdominal methods of nephrectomy. Each has its merits and its demerits, and M. Terrier has attempted to combine the merits of each without the corresponding demerits in a new method of operating. It consists in making a vertical lateral incision over the front of the kidney through the abdominal wall. The peritoneal cavity being opened, the diseased organ and the opposite one can be explored; and if the surgeon decides to proceed with the operation, he makes a clean vertical cut through the peritoneum over the kidney on the outer side of the colon, and strips up the serous membrane from the front of the kidney. By carefully suturing the cut edges of this visceral peritoneum to the edges of the abdominal wound, the field of operation is completely shut out from the general peritoneal cavity. Before doing this, the surgeon proceeds with the removal of the kidney. The vessels having been secured, the cut edges of the peritoneum are united as described above, and the ureter can be brought out at the lower end of the wound, which is then partially closed, a large drain being left in. The advantages of this method of operating are the facilities it affords for determining the condition of the opposite kidney, abundant room for extracting the kidney, ease in dealing with the pedicle, satisfactory drainage of the wound, which is rendered extra-peritoneal, and the freedom from risk of contaminating the peritoneum by the divided ureter. Terrier records the two cases in which he has practised this operation in the *Revue de Chirurgie* for May. One of them, in which there was hydronephrosis of the organ, was successful; the other, a case of malignant disease, was fatal. This method of operating certainly deserves further trial.

ANTI-VACCINATION.

THE article which we published recently on the instructions to public vaccinators issued by the Local Government Board is the subject of a letter in the *Echo* by Mr. William Tebb, a prominent leader of the anti-vaccination party, who, referring to our statement that "the amount of sickness and death which is prevented by this operation (vaccination) is almost incalculable," proceeds to say: "No evidence is produced to establish the truth of this wonderful salvation, for the very sufficient reason that there is none to produce, as all the available evidence both from England and the Continent points in an opposite direction." The anti-vaccinationists know too well that an assertion such as this appearing in the public press and left uncontradicted must have its effect amongst those persons who would never think of learning the lessons taught by every small-pox hospital, by the Registrar-General, by the Local Government Board, and by the State Departments of other countries. We have no reason to anticipate that any Government would deprive the country of the benefits resulting from the administration

Digitized by Google

of the Vaccination Acts; but the efficiency with which these Acts can be carried out is largely dependent upon the willingness of the people to protect their children by vaccination against small-pox. Under these circumstances, it becomes a serious question whether greater effort should not be made to combat such false statements as that to which we refer, and to enlighten the public as to the dangers of small-pox, and as to the immunity from this disease which is conferred by vaccination. It is indeed lamentable that a few anti-vaccinationists should be permitted to poison the public mind by assertions absolutely devoid of truth. The press, which publishes the letters of anti-vaccinationists, is not less open to those who are cognisant of the enormous saving of life which is effected by vaccination. There is no class of men who could better undertake this duty of the education of the public than medical officers of health, and no better service could be rendered by these officials than the constant delivery of lectures in their districts, which would thus enable the information, now too much confined to official publications, to be generally known. The Society of Medical Officers of Health are now considering changes in the constitution of their body which will add to its power of usefulness, and we would venture to suggest that the course we have indicated is one which they might readily adopt. They would be able to make clear to the public the absurdity of a story told in the same number of the *Echo*, that an unfortunate baby, who subsequently to vaccination suffered from diphtheria and whooping-cough, did not contract these diseases from its vaccination, and they would thus prevent the growth of an opinion based upon these fallacious statements. We do not doubt that if this method had been earlier adopted, we should have found the death-rates from small-pox much lower than they have hitherto been.

PARALYSIS OF CONVERGENCE IN TABES DORSALIS.

AN interesting case of paralysis of the movement of convergence of the eyes occurring at the commencement of tabes dorsalis, in a man aged thirty-six, has been placed on record by Dr. de Watteville in the *Neurologisches Centralblatt* (No. 10), and the facts of the case are also vouched for by Dr. James Anderson, whose examination corroborated the loss of knee jerk, loss of the light-reflex of the pupil, and the presence of accommodation, lateral and vertical movements of the globes, with perfect action of the eyelids. Loss of this function of converging the eyelids has been recorded as an isolated symptom, and as complicating Basedow's disease. Dr. de Watteville states that he knows of no observation in which this loss of convergence has been chronicled during the early stage of tabes, but he quotes Dr. Gowers' Manual, vol. i., p. 298: "Rarely there is loss of the movement of convergence associated with loss of accommodation, although the internal recti may act in the movement towards one side."

"WAKING NUMBNESS."

THE author of this communication to the *American Journal of the Medical Sciences* (April, 1887) proposes as a convenient designation for the "hitherto undescribed neurosis" the name of "narkophypnia," a suggestion which we trust will not receive general support. There is, he states, nothing but the sensation of numbness in these cases, no paralysis of motion or sensation, no change in temperature of the affected part, the surface is not blanched or mottled, and there is no tenderness on pressure. One case has been under observation six years; the patient, a professional man, aged forty-three, wakes up with a sensation of numbness which may involve both hands, arms, shoulders, thorax, and tongue. The sensation lasts no longer than one minute.

THE GORDON MEMORIAL.

EVERYONE who wishes well to the youth of the country will have learnt with satisfaction that the Gordon Boys' Home has, during its short but useful past, fully justified its claim to a continued existence. In the report submitted last week to the Council of this institution it was shown that the accommodation hitherto provided at Fort Wallington is fully occupied—a sufficient proof that the benefits afforded within its walls have been appreciated. Order, at one time somewhat difficult to establish, is now satisfactorily maintained, and, in spite of a considerable necessary outlay, self-help and economy have materially reduced the amount of working expenses, while the assets of the Home derived from funded property have largely increased. Just at this time, however, a large additional expenditure will be required for building purposes in connexion with the formation of the permanent establishment between Bagshot and Woking. This work has already been begun, and it is hoped that by next winter 160 boys will be in occupation of the new quarters. It is hardly requisite to remind our readers that the means at the disposal of the Council are still limited. They do not suffice to meet the whole cost of this scheme of extension. A greater sum than the available yearly income, indeed, is required to maintain the educational machinery in a thoroughly efficient state. The public are therefore invited to contribute in aid of this very deserving project. We cannot do better than advise them to accept the offer, and thus to prove at once their sense of what is really most practical in philanthropy, and their esteem for the memory of one who freely and most worthily spent his all and himself in their service. We note with particular interest that the new arrangements include the erection of a small detached infirmary, and for this purpose £1000 will be required. No part of the contemplated changes is more clearly desirable or even essential to the success of the scheme as a whole. No school of this kind can possibly be complete without its hospital, and the fact that this will be a separate building in the new Home is an additional guarantee that the management of affairs is in careful hands.

A POULTRY DEALER'S DEN IN THE EAST-END.

THE sanitary inspector of the Whitechapel District Board of Works has discovered a house in Spitalfields where the floor, bed, tables, and chairs were bespattered with filth due to the killing, drawing, and plucking of ducks and fowls. In the yard, in cages that did not seem to have been cleaned, there were a number of live poultry. The occupier of the house was a foreign Jew who deals in poultry. The odour of the rooms is described as most sickening, and the drainage arrangements as in a truly horrible state. Other rooms in this house were sublet and greatly overcrowded. Poverty, overcrowding, and defective drainage are bad enough of themselves, and too often characterise the houses where foreign Jews crowd together in the East-end of London. In this case, however, we have an additional grievance; and, at first sight, it seems difficult to explain how, under such unpropitious circumstances, a trade in poultry can possibly be established. Why should purchasers patronise this overcrowded and obnoxious private house instead of going to the market or to a clean shop? A ready explanation, however, can be given. It is a question of "Kosher" meat. The Jew must not eat poultry killed in the ordinary manner, and this poultry dealer buys live stock only, which he despatches in accordance with the rules laid down by the rabbi, and thus is able to trade with the Jewish community. The grievance may therefore be referred to the Jewish Board of Guardians and the Sanitary Committee they appointed shortly after the revelations we published concerning the sanitary condition

Digitized by Google

of the sweaters' dens in the East-end of London. The Jewish laws affecting the slaughtering of animals for human food were conceived with a view to the preservation of health. The poultry dealer in question may have observed the letter of these laws; but surely the condition of his house as described by the sanitary inspector is not in keeping with the spirit of the law. This obvious fact will commend itself to the more educated section of the Jewish community; and, for the health and credit of their race, measures will doubtless be taken by the Jews themselves to abate the nuisance.

THE FIELD OF VISION IN NEUROSES AND DURING THE MENSTRUAL PERIOD.

DR. L. FINKELSTEIN has drawn attention in a recent work to the effect of various neuroses and of menstruation upon the functional activity of the organs of sense, especially of the eye. Thus he found, from a large number of observations taken in Professor Merzheievski's clinic for nervous diseases in St. Petersburg, that in epilepsy, hysteria, neurasthenia, delirium tremens, and during menstruation the field of vision is perceptibly diminished in a concentric manner. In epilepsy the internal radius of the field is usually most affected. This diminution in the field of vision commences before the fit, simultaneously with the premonitory giddiness, headache, &c. The greatest diminution is, however, observed immediately after the fit; by the next day the field has always resumed its normal extent, no permanent effect having been detected in any of the cases examined. The field of vision for colours presented various anomalies, the diminution being most marked in the case of green, less for yellow and red, and least of all for blue. With regard to menstruation, it was found that the field begins to diminish from one to three days before the period, reaching its extreme limit on the third or fourth day of the flux, and returning to the normal about the seventh day. It varies in degree directly with the general condition of the woman and with the amount of blood lost. Here the diminution of the field of vision for different colours does not appear to vary, as in the case of epilepsy.

CHARGES AGAINST MEDICAL MEN.

IT is to be hoped that the almost uniform unsuccess of actions brought against medical men charged with offences against women, said to be committed in the course of the discharge of their professional duties, will lead women to be more careful in bringing such charges, and hysterical moralists to be more chary of stimulating women to fancy themselves injured. We would not say a word calculated to diminish carefulness on the part of medical men. Rather would we advise double caution in their professional relations with women. For example, we think it highly indiscreet in a medical man to administer an anæsthetic to a female patient without the presence of a third party. Also we think it very inconvenient and unfit that a medical man should have a habit of seeing patients in his bedroom. Such indiscretions perhaps show only the confidence of medical men in their own uprightness; but they are not to be approved for all that. Still, when all care is taken, our profession, from its very nature, will be exceptionally exposed to such attacks and actions as those under notice. The presence of third parties is a desirable condition of all consultations, but it is manifestly often impracticable, and the main stay of the profession must be on its own character and the delicacy of its own sense of honour and purity. Fortunately, there is a widespread confidence in the profession—a belief that it realises its responsibilities and appreciates the obligations imposed on it by the very interests with which it is trusted. This confidence is shown not only by the verdicts of juries, but by the observations of judges, and by the generous and respectful tone of articles in our lay contemporaries called forth by recent cases. We have been very much struck with this tribute to the profession, which may well lead every medical man to be doubly careful not to do anything that will lower the high standard of professional honour and morals, and it may well lead the medical bodies to deal boldly in expelling those who discredit their diplomas. The rarity of the necessity for such action on the part of the medical bodies is the best proof that the profession is still sound at heart and true to its great ethical traditions, which embrace "whatsoever things are true, whatsoever things are pure and of good report."

LONDON WATER SUPPLY.

A CONTEMPORARY, commenting on the machinery for the prevention of injury to health from London water supply, observes that, now there are half a dozen chemists and a Government water examiner engaged in this duty, if anything goes wrong the fact is not likely to escape notice. We have no doubt these gentlemen will do all in their power, but the staff is deficient in the one officer who could render most signal services to London; there is ample need for the employment of an engineer and of analytical chemists, but the subject which requires the most serious study is the effect of water upon the health of its drinkers. A medical man, skilled in sanitary science, is alone competent to undertake this duty, and Londoners should not rest satisfied until their interests are protected by the strengthening of the staff in this direction. The risks to London from the present methods of supply deserve to be immediately investigated, and every fact concerning them known; it will be little satisfaction to water drinkers if this should only be undertaken after a repetition of the calamitous experience of the year 1866.

COVERING WOUNDS WITH PLASTER.

AT an inquest held in the Southwark Coroner's Court last Friday a point was brought out which is of some importance as bearing on the treatment of recent wounds. A schoolboy running out of the school gates fell and cut his forehead. The wound was strapped with plaster, and everything appears to have gone well for four days. Then shivering came on, and was followed by drowsiness deepening into insensibility, and death resulted two days later. After a post-mortem examination, it was decided that the fatal issue was due to blood-poisoning brought on by neglecting to cleanse and dress the wound, the plaster never having been removed from the time of its application. In commenting on cases of this kind one naturally allows somewhat for the possible effects of shock occasioned by the primary injury, which, without amounting to any gross lesion, might yet materially influence the final result. Be this as it may, however, enough has been shown in evidence to enable the coroner to assign to the death in question a more direct connexion with the wound itself. The practice of plastering over recent cuts is very usual; it is also one which in numerous instances has proved injurious. Apart from any question of blood-poisoning, indeed, the mere tension of retained discharges is an inevitable source of mischief where this custom is adhered to. The simple rule in surgery which provides for the free escape of pus where such is likely to form is one of which we need not remind any qualified practitioner. Accidents due to neglect of this rule are chiefly liable to occur when a wound has been treated either by the injured person himself or by a practising chemist. In such cases plaster is the first resource, and is apt to be used rather well than wisely.

NEALE'S MEDICAL DIGEST.

THE second edition of this work, the first edition of which formed the seventy-fifth volume of the New Sydenham Society's publications in 1877, affords a means of ready information regarding such discoveries, new doctrines, and different methods of treatment in each department of medical science as are likely to be of interest to the practitioner. An appendix to the work has now been published, including the years 1882-3-4-5 and the early part of 1886. Originally intended for the daily and hourly use of the busy practitioner, there is hardly a case that one is called upon to attend in which valuable suggestions cannot be obtained by a simple glance at the pages of the Digest. We have already noticed Dr. Neale's work, but are induced again to call our readers' attention to the work for this reason: weekly, nay daily, we receive from correspondents queries, the answers to 99 per cent. of which are contained in this volume. All of us are conscious of valuable time having been lost in searching back numbers and wrong volumes of periodicals for what, after all, will most probably be missed, and to obviate such loss we can recommend to our readers no better method than reference to the Digest and its first Appendix.

SEASONAL RELATIONS OF CHOREA AND RHEUMATISM.

IN his paper on a partial study of the seasonal relations of chorea and rheumatism in the *Medical News* of Nov. 13th, 1886, Dr. Morris J. Lewis finds that while the chorea tracing shows a strong tendency to keep pace month by month with the irregularities in the storm tracing, that of rheumatism, while also strongly resembling the latter, may be seen to be exactly one month later, looking as if the effect of the meteorological changes was immediate in the case of chorea—as it is now acknowledged to be in some varieties of neuralgia—and preparatory only in cases of rheumatism. "From the close relationship known to exist between these two diseases one might be led to suppose that the rheumatism tracing would precede, or at least accompany, that of chorea, instead of following it, as this study seems to show."

ADULTERATION OF OIL AND LARD.

OLIVE OIL is adulterated extensively, and lard is also adulterated. These are among the latest discoveries of the daily papers, and for a day or two they have attracted some feeble indignation in the public mind. "How fraudulent—how disgraceful!" say a few, and then pass on to some other novelty. Of course, oil and lard are adulterated. No one who knows anything of the trades doubts it. Dishonest vendors are making profits freely by their dishonesty, but nothing noxious is sold to the public, and as for the fraud, who cares? Certainly not the Government, who are too busy to think of such things, and certainly not the public, who are too apathetic to care about anything that does not come before them with a flourish of trumpets. The British consul at Leghorn has recently made some strong remarks on the barefaced frauds now openly perpetrated in Tuscany and England. Not only is olive oil freely adulterated with the cheaper oil of cotton seed, but the well-known flasks and cases are now sent empty to London to be filled with cotton seed oil and sold in England as olive oil of fine quality. It may well be asked, Is there no possible remedy for such audacious swindling? Of course there is; the remedy is simple enough. The adulterations of olive oil can easily be detected, and fraudulent vendors might easily be punished if it were not for the absurd difficulties which are engendered by our English law. Give us a more stringent Adulteration Act, which shall not only confer greater power upon local authorities, but compel them to exercise it, and such frauds would soon become matters of history. At present, however, there seems little chance of such an upheaval of commercial morality.

LEUCOCYTOSIS AND NEW GROWTHS.

ALMOST any sudden or rapid change in the organism appears to be attended with an increase in the white blood corpuscles. In fevers, inflammations, and especially suppurations, a leucocytosis may always be detected. A careful paper on this subject was communicated to the Royal Medical and Chirurgical Society by Mr. T. P. Gostling two years ago. Hayem has recently read a paper on the leucocytosis accompanying the development of neoplasms. A cubic millimetre of blood should yield normally 6000 white blood corpuscles, but the numerical fluctuations are greater for white than for red blood corpuscles. Hayem, assisted by M. Alexandre, draws the following conclusions:—Scirrhus and encephaloid cancers are accompanied by a slight increase in the number of white blood corpuscles. The leucocytosis is much more marked with osteo-sarcoma and lympho-sarcoma. Epithelioma has the least influence in inducing an increase in the white corpuscles. Hayem believes that the leucocytosis may prove of diagnostic service, and mentions a case of doubtful epithelioma of the foot in which M. Alexandre counted 14,000 white globules per cubic millimetre; it was thought during the life of the patient, from this circumstance and from the absence of inflammatory complications, that the disease might be cancerous. The case terminated fatally after operation, and the necropsy revealed several visceral neoplasms of encephaloid structure

ANOTHER DEATH ON A TRICYCLE.

CLOSELY following the death of Prof. Hack of Freiburg on a tricycle, a well-known inhabitant and parochial official of Plumstead has met with a similar end. On the Queen's birthday he rode out into the country, and after having ascended a hill near Sidcup, and while going steadily along a level road, smoking according to his usual practice, he was seen to fall from the machine. The bystanders appear, unfortunately, to have attempted to raise him into a sitting posture against the bank, and he died in a few minutes. According to the published report of the inquest, the medical evidence was to the effect that "all the organs of life were healthy, and that death had been the result of syncope produced by over-exertion after a hearty meal." The deceased was fifty-five years of age. Healthful as cycling is for those who are young and strong, with an unimpaired condition of the circulatory organs, it becomes a dangerously severe exercise for persons who, besides being somewhat advanced in life, have any cardiac or arterial mischief, and if indulged in to the point of riding up hills immediately after a heavy meal fatal consequences may very easily ensue.

THE LATEST CURE FOR CONSUMPTION.

THE recent observations of Dr. Kolischer upon a new method of treating tuberculous disease of joints, which were described by our Vienna correspondent last week, appear to have excited considerable attention. The method, based on the fact that tubercle deposits do sometimes undergo spontaneous "cure" by calcification and fibroid changes, was an endeavour to excite such retrogressive change artificially. The results obtained in the few cases at present thoroughly treated were certainly striking, and were declared by Professor Albert to surpass any other plan of treatment yet in vogue. It is now said that Dr. Kolischer contemplates applying the same method to the treatment of visceral tubercle, and once more the world is agitated by the

Digitized by Google

alleged discovery of a "cure for consumption." We would counsel a little patience before accepting even the possibility of being able to artificially arrest the progress of pulmonary phthisis by the administration of acid phosphate of lime or any other salt. At the same time, we would by no means discountenance a fair trial of any plan which, as in this case, is based on rational grounds. Perhaps between the varied efforts to discover germicidal agents on the one hand, and drugs to render the tubercular neoplasm obsolete on the other, we may one day arrive at some panacea. There is not much, however, in the recent history of the treatment of phthisis to render us very sanguine of such a result being attained.

CLINICAL SOCIETY.

AT the last meeting of the Clinical Society a vote of thanks to the Committee for its report on the connexion of joint disease with locomotor ataxy was proposed by Dr. J. G. Glover, seconded by Dr. Ormerod, and agreed to with acclamation. The President said that the report was a most valuable one, and would reflect great credit on the whole Society. The names of Sir James Paget (chairman of the committee) and of Mr. Bilton Pollard (the hon. sec., on whom it is understood a considerable amount of work fell) were specially mentioned in the vote of thanks. Mr. Bilton Pollard thanked the Society on behalf of the committee, and said that the report comprised the results of observation of a large series of cases of joint disease in locomotor ataxy and of ordinary osteo-arthritis, and, so far as the cases allowed, he thought the report went far in the direction of settling points raised in the debate.

VACCINATION IN NATAL.

THE precautions necessary to be observed against small-pox epidemics appear to be sadly neglected in Natal. At the last half-yearly meeting of the Vaccine Board it was stated that forty-eight births had been registered in the Newcastle division during the latter half of last year, and, as far as could be ascertained, not one of these children had been vaccinated.

A CASE OF HYDROPHOBIA.

A CASE of hydrophobia was admitted into St. Thomas's Hospital on May 16th. The boy, aged six, was bitten by a dog over the left eye two years ago; the wound was not treated in any way; he was quite well until the evening of the 15th ult., when he was observed to be rolling on the floor, and soon refused food and drink. He was admitted on the evening of the 16th, the symptoms then being a peculiar jerky inspiration with a condition of great terror and excitement. He soon developed well-marked symptoms, having general convulsions on attempting to drink, and constantly ejecting saliva from his mouth. He was quiet and sensible between the paroxysms, complaining of toothache on the left side. He died on the evening of the 17th from cardiac and respiratory paralysis.

NO MEDICAL EVIDENCE.

AN inquest was held on May 24th by Mr. William Carter, at York-street, Lambeth, touching the death of Sarah Clara Watson, aged fifty-one years. From the evidence, it appears that the deceased had been addicted to habits of intemperance for twenty years. On the day of her death she called up her son, and complained of feeling ill. A glass of wine was given to her, and immediately afterwards she fell prone on to her bed, and appeared to sink into "a sound sleep." Two hours later it was discovered she was dead. No medical man was sent for, nor was any medical evidence called for at the inquest. The deceased appears to have manifested some delusions shortly before her death, and it is not at all improbable that she had delirium tremens, and that she died from sudden failure of the heart's action—an issue not very uncommon in that affection. Moreover, long indulgence in alcohol is calculated to produce fatty degeneration of the heart's substance, and this may have conduced to the fatal event. At the same time, we cannot but think that a medical man should have been summoned when the deceased was found to be dead, or apparently dead, and that the case was one in which a post-mortem examination should have been made. In every case of sudden death, where the cause is not obvious, the jury should have something more than probabilities to guide them.

NEPHRO-LITHOTOMY IN AUSTRALIA.

DR. W. GARDNER, surgeon to the Adelaide Hospital, reports a successful case of nephro-lithotomy, which is of special interest as the first case in which this operation has been performed in Australia. The patient was a man twenty-three years of age, who dated his troubles from a fall, which was immediately followed by hæmaturia. For three years he suffered from pain in the left loin and testicle, hæmaturia, and frequent micturition. There was marked tenderness of the left kidney. Dr. Gardner cut down on to this organ from the loin, found a stone in it, and removed it. The calculus was composed of oxalate of lime. The patient made a good recovery. It is satisfactory to find that the value of this operation is appreciated in our far-off colonies, and that they are supplied with surgeons so alive to the advances made in Europe, and so well qualified to give their patients the benefit of them.

INFANTILE DIARRHŒA.

THE latest recommendation for the treatment of the "green diarrhœa" of infants is that of M. Hayem, who has tried with much success the hydrochloric and lactic acids, the latter being preferred. A teaspoonful of a 2 per cent. solution of lactic acid is given after each stool, as much as from forty to sixty centigrammes a day being taken by the infant. M. Lesage has investigated the stools and has discovered a microbe, which will probably receive more attention. The activity of this microbe is diminished by acids, hence the explanation of the value of the above treatment.

MR. LUND, F.R.C.S.

WE regret to hear that Mr. Lund, whilst engaged last Saturday in his duty as an examiner in the Final Fellowship, was seized with a slight attack of an apoplectic nature. We are very glad, however, to be able to state that he is now so far recovered as to be able to leave his bed, and will after a few days' rest probably be able to resume his professional duties.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Emil Huber, Extraordinary Professor and First Assistant in the Leipsig Pathological Institute.—Dr. Ferdinand Hauska, Emeritus Professor of Medical Jurisprudence in Vienna.—Professor Hamernik, of Prague, in his seventy-seventh year.—Dr. Jewell, Professor of Neurology and Mental Diseases at the Chicago Medical College.—Dr. Alexander Ecker, Professor of Anatomy in Freiburg.—Dr. François Vleminckx, secretary of the Brussels Medical Federation.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Professor Senator has succeeded Professor Henoch in the charge of the clinic for children's disease, Professor Henoch being obliged to retire on account of ill health.

Buda-Pesth.—Drs. Jendrassik and Moravcsik have qualified as *Privatdocenten;* also Dr. Pertik, Prosector of the new City Hospital.

Leipsig.—Dr. Winkler, of the Freiburg Bergakademie, has been appointed Professor of Chemistry, with the charge of the physico-chemical laboratory, in succession to Professor G. Wiedemann.

MESSRS. LONGMANS AND CO. announce as almost ready for publication the following amongst other new books and new editions:—A Text-book of Elementary Biology, by R. J. Harvey Gibson, M.A., F.R.S.E., Demonstrator of Biology in University College, Liverpool; Modern Theories of Chemistry, by Professor Lothar Meyer, translated from the fifth German edition by Messrs. Bedson and Williams; a new edition of Huth's Marriage of Near Kin; Electricity for Public Schools and Colleges, by W. Larden, M.A.; and Elements of Physiological Psychology, by George T. Ladd, Professor of Philosophy in Yale University.

IT is satisfactory to learn that the Home Secretary has advised Her Majesty to commute the sentence recently passed upon the two prisoners at Warwick Assizes for having caused the death of a young woman by procuring abortion. As we remarked last week, heinous as is the offence of criminal abortion, there are yet certain features in connexion with this case which seem to show that justice will be satisfied with a less penalty than the highest the law can inflict.

ON Wednesday, at the French Academy of Medicine, Sir T. Spencer Wells was elected Corresponding Foreign Member, "*à la presque unanimité des suffrages*"; and last month he received the diploma of Honorary Fellow of the German Society of Surgery, conferred at their sixteenth Congress.

WE are requested to inform subscribers to the Jacob testimonial that the presentation of the address and purse of 500 sovereigns will be made at 5 P.M. on Monday, June 6th, at the Royal College of Surgeons, Dublin.

MR. A. MARMADUKE SHEILD, M.B., B.S. Cantab., F.R.C.S. Eng., assistant surgeon to Westminster Hospital, has been elected an assistant surgeon to Charing-cross Hospital.

THE ninth annual congress of the American Laryngological Association was held at New York on the 26th ult. and two following days.

UNIVERSITY COLLEGE, LONDON.

THE distribution of prizes by the Faculty of Medicine of the London University College took place on Wednesday, when Sir George Young, Bart., presided. There was a large attendance of professors and students. After the reading of the report by the Dean of the Faculty and the presentation of the prizes,

The CHAIRMAN addressed the students. He congratulated the recipients of the prizes, and after referring to the past work of the College and the loss sustained by the death of Dr. Wilson Fox, he alluded to the establishment of the Victoria University, its general objects, and its effects on the London University College. He pointed to the fact that a number of medical students in London were in the habit of going to the provinces to qualify by residence at some other school for the attainment of the degree which the authorities of the school had power to give. Admitting that there were teachers elsewhere as eminent as those in London, why should he hesitate to say, when it was universally acknowledged, that there was no medical school in the kingdom which could claim a higher tradition of successful teaching than their own, that the general hospitals of London with their eleven medical schools afforded a field for study which it was ridiculous should be deserted for other fields under the stress of artificial regulations? Not only were medical schools dependent upon hospitals, but hospitals were dependent upon them. Each school had to provide not merely the clinical teaching which the hospital wards supplied, but scientific instruction of a multifarious and costly character. When a school was a constituent of a general college the instruction was ready to hand, but elsewhere it was too often improperly provided. Most of the lesser schools had lately acknowledged their insufficiency, and had entered into an arrangement with the Government School of Science at South Kensington to get that part of their work done for them. To that arrangement the Council of the College took exception on account of its exclusive character. A remedy for the existing evil was needed which should put an end, not to wholesome emulations, but to the mischief which proceeded from their excess, which would enable other schools, without fear of losing ground, to permit their students to come to the London University College for scientific instruction, and which should bring together the teachers and administrators of the schools to concert, on equal terms, on a common platform, with the University, means for the improvement of medical education. Considerations of that nature had led to the movement for a Teaching University in and for London, which had now been brought to a practical stage of definite proposals and a formal programme. They asked that the same privilege which had been conceded to the country colleges through the Victoria University should be conceded to them. They wanted a degree giving authority, in which their administrators and teachers should have their due share of influence. They wanted a new institution—a federation of the University colleges and medical schools in the London district—whereby measures might be arranged, in concert, for the promotion of university education. They could not go to Manchester, or so far give up their position and history as to apply for admittance to the offspring of their offspring. To do so would be to accept a position in a university of an imperfect type, when the perfect type of a localised university was open to them. If the population of this vast metropolis was not sufficient to support a university, what population was? The last report of the Senate Committee of the London University had been carefully considered by the College, but its proposals did not amount to the foundation of anything analogous to a Teaching University for London. They were limited to the admission on the Senate of eight representatives of bodies called Faculties, which were again to be composed of the representatives of the teaching institutions throughout England sending up students to the University examinations. There was also a provision for Boards of Studies, and there was to be an addition to the preamble including among the purposes of the University "the promotion of regular and liberal education throughout Her Majesty's dominions, and especially in the metropolis and its neighbourhood." There was, finally, a proposition that the University was to be at liberty to found professorships and lectureships provided they were not of a kind likely to compete with the University College. The proposals, however, were of a very meagre character: nothing was done for the organisation of university education in London. The Boards of Studies, the Faculties, and the new members of Council did not belong to London, but to England at large, and they could not meet the evils that had been pointed out. They tended to interfere with the position of impartiality which the University was bound to maintain. By mixing up the system of an Examining University with the system of a Teaching University they ran the risk of spoiling the work the University was doing, and they were quite certain not to do well the work that was waiting to be done. The real work of a Teaching University was not merely to provide for, but to commend to its students, the best methods of study under the best teachers; in the Examining Univer-

Digitized by Google

sity the degree was only the mark of attainment. The two systems were not compatible. But if mutually destructive when blended in one institution, there was room for them both. There was plenty of room for an Examining University in the British Empire. Even though a certain proportion of its candidates from London institutions were withdrawn, there would still be plenty of candidates for its degrees, and plenty of honour attaching to them. But why should institutions like the London University College be for ever debarred from the right to confer, under proper guarantees, the honour of a public degree? They asked that a charter to confer degrees upon all persons who had undergone a regular course of study in a college or medical school of the University, and had passed the required examinations, should be granted to a suitable governing body upon which the governing bodies of University College, of King's College, and of the teaching staff, not merely of those Colleges, but of other medical schools, should be represented. To this end they sought an alliance with the Royal Colleges of Physicians and Surgeons, thus offering guarantees to other medical schools that their interests would be respected. It had been objected that the degrees of the London University having been kept at a high standard, the degrees of the new University would not be kept as high. He did not deny that it was one of their objects that degrees should be more easily obtained by London medical students. There was always some work thrown away in preparing for the best of examinations, and in preparing for an examination against which great objections were urged, which was arranged independently of the teachers who prepared for it, the amount of friction and wasted work was considerable. Assuming that a London degree represented higher attainment than an Edinburgh or a Cambridge degree, that was an excellent thing for the University and for those who attained its degrees, but it was a bad thing for the much greater number who gave up all hopes of a degree, but who might have been stimulated to meritorious exertions for a prize which was within the reach of effort. It was a still worse thing for youths who ran away to Newcastle, because they foresaw that in country practice they would be at a disadvantage beside the Newcastle men. The next objection was that the professors wanted to "brand their own herrings," that the defects of their teaching should be concealed by the Government stamp, which was placed in their own power to confer. That accusation was a mistake. The University system to which more than any other the accusation applied was that of the University of London. Again, it had been urged that the establishment of a new University with power to confer degrees with a licence to practise was objectionable as increasing the number of bodies conferring such licences. The remedy would be easy if a cordial alliance could be established with the Royal Colleges. There would be no interference with their prerogative and no addition to the number of licensing bodies. There was at present a movement on foot at the College of Physicians for a single Faculty university in London, or an institution in the nature of a university to confer medical degrees alone. That movement appeared to the London University College to be part of its movement. Regarding it as a separate movement the College could not look upon it altogether with approval, as it would be fatal to its medical school; but if the movement of the Colleges of Physicians and Surgeons could be brought into line with that of the University College, then, indeed, they would have obtained a very large part of what they sought. No doubt there were great difficulties to be encountered. Some of their number, including their President, and others who had held high office, had thought it their duty to withdraw from the Council of the College. They had, however, encouraging assurances from influential quarters of sympathy with the movement, and they would, no doubt, soon be in a position to fill up satisfactorily their depleted ranks. Those who remained were not discouraged; they were now unanimous amongst themselves; they had the unanimous support of the professors; they had the unanimous voice of King's College, once their rival but now their cordial ally; they had friends in the press, in every medical school in London, and every university in England. They believed in the future capabilities of the institution, and they desired to make it greater than it was at present, more splendid, more efficient, and in that aim they expected to succeed, because they were not labouring only for their own aggrandisement, but towards the foundation of a university which would be of incalculable benefit to the cause of education in the mighty metropolis in which they lived. (Loud applause.)

On the motion of Mr. ERICHSEN, a vote of thanks was passed to Sir G. Young for his address.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

WE have received from the Secretary of the College for publication the subjoined abstract of the petition to the Queen for a Supplementary Charter. Copies may, we understand, be obtained on application by Fellows and Members of the College.

The following are the purposes for which the application is about to be made:—

1. To enable the College to hold "lands, tenements, rents, and hereditaments" of an annual value not exceeding £20,000, instead of £2000 as by present Charter.

2. To enable the Council to determine by rules and regulations, instead of, as at present, by bye-laws, the conditions of admission to the Fellowship by examination; and to determine by bye-law, instead of by Charter, the fees payable for such Fellowship.

3. To empower the Council to elect to the Fellowship Members of twenty years' standing, not exceeding ten (instead of two) in each year, on the payment of the same fee as required for the Fellowship by examination.

4. To authorise the election by the Council of any number of persons, not exceeding two in each year, whether a Member or Members of the College or not, having, in the opinion of the Council, to be ascertained and expressed in such manner as the Council may from time to time think fit and direct, rendered distinguished service in the advancement of surgery or the sciences allied thereto, such persons to be and be called Honorary Fellows. Such Honorary Fellows not to pay any fee, and to be ineligible to vote for the election of members of the Council.

5. To provide that Fellows may vote in the election of the Council either in person or by voting papers, such papers to be signed, authenticated, and delivered in such manner as the Council shall from time to time think fit and direct. No election of members of Council to be valid unless there shall be present at the meeting for the purpose of such election such number of Fellows as the Council may from time to time think fit and direct.

6. To render Fellows of ten (instead of fourteen) years' standing eligible for election as members of Council, and to abolish the restriction in regard to their practising as apothecaries.

7. To simplify the mode of nomination of Fellows, candidates for election to the Council, by requiring in each case only one nomination paper to be signed by three Fellows.

8. To dissolve the Midwifery Board.

9. To enable the Council to increase the number of members of the Board of Examiners in Dental Surgery, and to require that those members of the Board described as "persons skilled in Dental Surgery," who shall in future be elected, shall be persons registered under the Dentists Act of 1878.

May 23rd, 1887. EDWARD TRIMMER, Secretary.

HEALTH OF ARMY HORSES.

THE annual statistical and general report of the principal veterinary surgeon of the army, for the year 1886 has just been issued, and is of a very satisfactory character. The mean strength of the army horses at home was 12,393; the admissions on the sick list during the year were in the proportion of 628 per 1000; the deaths from all causes were 18·8, of which 12·5 were the result of disease and 6·3 were destroyed for various causes. The proportion cast and sold amounted to 87·5, and the constantly non-effective from disease and injury to 38·0 per 1000 of the strength. Compared with the preceding year's results, the admissions were slightly higher, the deaths and constantly non-effective were identical, and there was a slight decrease in the number cast. The Royal Engineers furnished the highest proportion of cases, amount-

Digitized by Google

ing to 825, and the Life Guards the lowest, being only 428 per 1000. The highest death-rate (25·3) was in the Heavy Cavalry, and the lowest (14·4) in the Field Artillery. The increase in the admissions has been chiefly from diseases and injuries of the locomotive apparatus, particularly contusions, sprains, and diseases and injuries of the feet; there has also been an increase in diseases of the digestive apparatus, especially colic, and in strangles and epizootic fever. Only one case of glanders occurred; it was in a remount of the 13th Hussars at Colchester, which had just joined from Ireland, where, it is believed, the disease was contracted. The 2nd Life Guards in Regent's-park Barracks had 65 cases of epizootic fever, being in the ratio of 247 per 1000 of the strength, and nearly half of the admissions from this cause in the whole force. The only other stations at which it prevailed to any extent were Canterbury and Aldershot, which respectively had 20 and 45 cases, or 53·7 and 21·9 per 1000 of strength. Dr. Fleming does not assign any reason for this outbreak in the 2nd Life Guards, but he remarks: "It will be noted that the Regent's-park Barracks, London, continues to be by far the unhealthiest of all the stations for mounted corps in the United Kingdom, the average sickness from zymotic diseases being 24·71 per cent., the next highest being Canterbury, with 5·37 per cent., and the next Aldershot, with 2·19 per cent." Previous reports, however, do not quite bear out this statement about the Regent's-park Barracks, and it is noteworthy that in every year in which they have been recorded as furnishing such cases they have been occupied by the 2nd Life Guards. The immunity of the 1st and liability of the 2nd Life Guards to these diseases is a subject worthy of investigation. A case of rabies occurred in a horse of the 1st Life Guards three months after he had been bitten at Wormwood Scrubbs, although cauterisation of the wound had been immediately resorted to. The highest annual ratio of admissions occurred among the four-year-olds, and the deaths among them were twice as high as at any age up to seventeen—results in accordance with those of previous years.

The proportion of horses cast has been lower than in any of the preceding four years, but their average service has also been lower, having been only seven years and seven months, while in previous years it has usually been a little over nine years. Nearly one-third were cast for "old age." The average price received for them was £10 0*s.* 9*d.*, which, although a trifle higher than in 1885, was considerably under the prices of preceding years.

In addition to the information respecting the horses in the United Kingdom, the report contains, for the first time, returns of the horses, mules, and camels in charge of the veterinary officers in Egypt and in Natal. The results for the animals in Egypt are shown in the following summary:

	Average strength.	Ratio per 1000 of strength.			
		Admitted.	Died.	Destroyed.	Total loss.
Horses ...	1191	822	18·5	24·3	42·8
Mules... ...	948	340	9·5	9·5	19·0
Camels ...	615	1691	297·5	42·3	339·8

The admissions of horses were not excessive, considering the circumstances under which they were employed; two-thirds of the cases were of injuries and diseases of the locomotory apparatus and surgical diseases and accidents. Digestive diseases, chiefly colic, were next in frequency, and then general diseases, of which more than half were returned under the heads of anæmia and asthenia. The most fatal diseases were those of the digestive apparatus, causing eleven deaths, of which four were from colic and four from enteritis. The colic "was, in many instances, due to the horses eating sand, usually with their food." There were only nine cases of glanders, which were, of course, at once destroyed. Considering the great prevalence of this disease in Egypt, the army horses appear to have been very fortunate.

The mules furnished a very low ratio of cases and of deaths. The diseases from which they suffered were much the same as those of the horses, but they had only two cases of glanders.

The history of the army camels, as shown by these returns, is a very melancholy one. The proportion of cases and of deaths was extremely high. Of the former, two-thirds were cases of sore back from the saddles, and one-fifth was returned as asthenia and exhaustion. Surely there must have been gross neglect somewhere to permit of such results. Of 209 camels which died or were destroyed, 178 are accounted for under the head of asthenia and exhaustion. On this disgraceful state of matters Dr. Fleming prudently refrains from comment.

The strength of animals employed by Government in Natal is stated at 732 horses and mules, but the numbers of each are not given separately. The cases among them amounted to 759, and the total mortality to 142·0 per 1000 of the strength. Of the ninety-one animals which died, sixty-one were returned under the head of anthrax, and seven of intestinal calculus caused by the horses eating sand. Of "anthrax" Dr. Fleming says that "in some parts of the most fertile portion of the Cape and Natal colonies it is impossible to keep horses during the summer season, nearly all perishing from this plague." Of seventy-one army horses and mules attacked during the year under review, only ten recovered. The Government has sent out a veterinary officer, who has gone through a special course of training, to investigate the nature of the disease "and to attempt its suppression by the adoption of the method of protective inoculation with attenuated or modified virus, introduced by Pasteur and others so successfully in the case of European anthrax." We shall look forward with much interest to the result of these experiments.

In addition to the information on the subject of the health of the army animals at home and abroad, the report gives an interesting account of the good work going on in the Army Veterinary School at Aldershot. The instruction given in it is not confined to the veterinary officers, but is open to any officers of the garrison who may choose to avail themselves of it. A considerable number have taken advantage of it, and there can be no doubt that the knowledge thus acquired may prove most useful in a campaign and in the colonies. The school is also turned to account in training a body of farriers to act as veterinary assistants or subordinates—a system which has already been found to work advantageously on service in Egypt and South Africa. Dr. Fleming has given some details of his proposed farriery reorganisation, which appears calculated to diminish the labour and increase the efficiency of the department; and also a short but interesting article on winter shoeing, which we recommend to the attention of all who require to use their horses in winter, whatever the weather may be. The careful manner in which the report has been drawn up, and the practical character of the suggestions it contains, are worthy of Dr. Fleming's reputation, and the satisfactory state of health of the army horses reflects credit upon the department over which he presides.

ARMY MEDICAL STAFF DINNER.

THE annual dinner of medical officers of this department was held at the Holborn Restaurant on June 1st, Sir Thomas Crawford, K.C.B., in the chair. The following officers and guests were present:—*Inspectors-and Surgeons-General:* Lawson, Balfour, Gordon, C.B., Ker Innes, C.B., Sir T. Longmore, C.B., Massy, C.B., Manifold, Fraser, Mackinnon, C.B., Irvine, Hendley, C.B., Ekin, C.B., Muschamp, and Fuller. *Deputy Inspectors-and Surgeons-General:* Swettenham, Laing, Fox, Fraser, Reade, C.B., Marston, Roberts, Veale, Watts, Sly, and Don. *Brigade Surgeons:* Ashton, Herbert, Wade, Inkson, Warren, Prescott, Gribbon, Maunsell, Wright, Leask, Mackinnon, Lloyd, Adcock, Tomlinson, Clarke, and Anderson, C.I.E. *Surgeons-Major:* Lane, Churchill, Hensman, Staples, Maunsell, Scott, C.M.G., O'Dwyer, McNalty, Nash, Beattie, Johnston, Macartney, Morgan, McSwiney, Macrobin, Frazer, Roe, Clery, Williamson, Ash, Donovan, Buske, Allin, Miller, Gormley, Scott, and Powell. *Surgeons:* Ligertwood, Fenn, Ryan, Tuthill, Kirkpatrick, Seymour, Clark, Flood, Harwood, MacNeece, Baker, Twiss, Sloggett, Porter, Johnston, Reade, Semple, Carte, Sheldrake, Zimmerman, Bostock, Hale, and Minniece. *Guests:* Sir Charles McGrigor, Bart., Sir J. W. Reid, K.C.B., Sir William Mac Cormac, Inspector-General Dale, Dr. Glover, and Messrs. Pollock, Holt, and Hart.

The health of the Director-General of the Department was proposed in very warm terms by Sir William Mac Cormac. In reply, Sir Thomas Crawford said that he was ambitious

Digitized by Google

mainly to effect two results—first, to hold high the standard of professional efficiency and character in the army, and, secondly, to approximate more and more the military and the civil branches of the medical profession.

HYDROPHOBIA AND THE PASTEUR INSTITUTE.

ACCORDING to the report of the late Dr. Vulpian, the secretary, the number of persons subjected at the Institute to the Pasteur treatment during the fourteen months from the end of October, 1885, to the end of December, 1886, was in all 2682. Of this number 2164 had been bitten by animals known for certain to have been mad at the time of biting, and the remaining 518 by animals suspected to have been mad. Of the 2164 bitten by animals undoubtedly mad and treated according to Pasteur's method, 29 persons died, representing a proportionate mortality of 1·34 per cent. Of the 518 bitten by animals presumed to be mad, and subjected to Pasteur's treatment, only 2 died—i.e., 0·36 per cent. The statistics of rabies before the discovery and application of the Pasteur method give the proportion of mortality from that disease among the persons affected by it as at lowest 16 per cent. If, then, this percentage be correct, the cases of mortality amongst the 2164 persons in the state described, had they not been treated by the Pasteur method, would have been, not 29, but 346. With respect to the most dangerous cases, the report states that there were 48 persons bitten by mad wolves, 186 persons bitten on head or face by animals known to be mad, and 28 bitten on head or face by animals presumed to be mad. Of the 48 in question 7 died—i.e., a mortality of 14 per cent. The mortality in similar cases before the Pasteur method is ascertained to have been 60 to 80 per cent. Moreover, in three of the 48 persons symptoms of rabies had actually appeared before the application of the treatment, and their deaths may therefore be left out of account, thus reducing the mortality of this class under the Pasteur treatment to 8 per cent., as against 60 per cent. to 80 per cent., without this treatment. Of the 186 above specified, the number of persons who died was 9, or 4·83 per cent., as against 88 per cent. without the Pasteur treatment. That is, out of the 186, 163 would have died but for this treatment, whereas under its employment only 9 died. Lastly, of the 28 above specified, only 1 died—i.e., a mortality of 3·57 per cent. For some months past M. Pasteur has modified his method, and in the most serious cases has applied, not simple, but intensive treatment. And whereas out of the 136 specially serious cases in which the simple treatment was applied 9 died, in 50 specially serious cases in which intensive treatment was applied no mortality whatever is stated to have followed.

BIRMINGHAM MEDICAL BENEVOLENT SOCIETY.

THE sixty-fifth annual general meeting of the Birmingham Medical Benevolent Society was held on May 27th, Dr. James Johnston in the chair, there being a good attendance of members. Dr. Thomas Savage, hon. sec., read the annual report of the directors, which stated that during the past year the Society had accomplished its usual amount of work in a quiet, unostentatious manner. The invested funds at the end of 1886 amounted to £10,978. During the year fifteen annuitants had received grants varying in annual value from £10 to £40. The roll of benefit members contains 272 names, the total receipts during the year reached £615 2*s.* 4*d.*, and grants had been made to the amount of £465. A new annuitant, a member of the Society, had been added to the list, and a grant of £40 a year had been made. The widow of a deceased member had also been made an annuitant. Since the commencement of the present year the widow of a deceased member had died. She was in receipt at the time of her death of £25 a year, and had received a total of £837 10*s.* from the funds of the Society. Her husband had paid as a member of the Society seventeen guineas. Twelve new members had been elected, and six had died. Mr. Alfred P. Evans (West Bromwich) was appointed president; Dr. Charles Warden, president elect; Mr. Arthur Oakes (Birmingham) and Mr. J. Arthur (Henley-in-Arden), vice-presidents; Dr. Marriott (Leamington), Mr. Priestley Smith, and Mr. Wm. Thomas were added to the directorate; Mr. Bartlett and Sir James Sawyer were reappointed treasurers, and Dr. Thomas Savage was re-elected honorary secretary. The members afterwards dined at the Grand Hotel, under the chairmanship of Mr. A. P. Evans.

WILLS OF MEDICAL MEN.

THE will of Surgeon-General William Rutherford, M.D., C.B., honorary physician to the Queen, late of 325, Vauxhall-bridge-road, who died on March 24th last, was proved on April 27th by Mr. Peter Ronaldson and Mr. George Ronaldson, the executors, the value of the personal estate in the United Kingdom amounting to upwards of £49,000. The testator bequeaths £500 to the Dublin Lying-in Hospital, and numerous legacies to relatives and others. The residue of his property he leaves between the children of his late first cousin Thomas Shirreff Rutherford, and three of the children of his late first cousin George Rutherford.

The will and codicil of Dayrell Joseph Thackwell Francis, M.D., F.R.C.P., formerly of Northampton, and late of Wethersell Grange, Cranleigh, were proved on April 26th by Herbert Howard Keeling, Mrs. Marian Howard Francis, the widow, and the Rev. Edward Howard Francis, the son, the executors, the value of the personal estate amounting to over £30,000. The testator, after giving legacies to sons and to his trustees, leaves all his real estate and the residue of his personal estate upon trust for his wife for life or widowhood, and then for his children.

The will of John Jackson, M.D., a retired officer of the East India Company in their Bengal establishment, late of 5, Brunswick-terrace, Brighton, who died on March 31st last, was proved on April 23rd by Mr. Herbert William Fisher and Mr. Charles Nottige Macnamara, the executors, the value of the personal estate amounting to over £15,000. The testator gives all his household furniture and effects and £500 to his wife, £50 to each of his executors, and several legacies to brother and sisters. He also leaves £10,500 upon trust, to pay the income to his wife for life, and, after her death, upon the trusts of the marriage settlements of his three daughters. The residue of his property he bequeaths to his wife absolutely.

Letters of administration of the personal estate of Thomas Allen, M.D., late of 11, Keppel-street, Russell-square, who died on March 21st intestate, were granted on April 28th to Mrs. Emma Allen, the widow and relict, the value of the personal estate amounting to upwards of £14,000.

The will of Mr. George Curme, late of 9, Cornhill, Dorchester, surgeon, who died on January 2nd last, was proved on March 10th by Mr. Decimus Curme and Major-General Joseph Hanwell, the executors, the value of the personal estate amounting to £8500. The testator bequeaths all his household furniture, wines, &c., and under his marriage settlement gives his houses in Cornhill and £3500 consols, to his daughter; his surgical books and instruments and his Ross's microscope, with all the fittings, to his nephew, Mr. Decimus Curme; and legacies to servants. His estate at Whitchurch and the residue of his personal estate he leaves upon trust for his daughter for life, and after her death, subject to certain conditions, to Decimus Curme and his sons.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. George Henry Johnson, late of 10, Addison-crescent, Kensington, £105 each to the Chelsea Hospital for Women, Queen's Elm, Brompton; the Metropolitan Free Hospital, 81, Commercial-street; St. George's Hospital, Hyde-park-corner; the West London Hospital, Hammersmith; St. Mary's Hospital, Paddington; the North London or University College Hospital, Gower-street; and the Middlesex Hospital.—Mr. Robert Cocks, late of Wilby House, Ladbroke-terrace, Notting-hill, £200 to the Gloucester Hospital.—Mr. John Bowie, late of the Beacon, Exmouth: The testator gives and bequeaths all such parts of his personal estate and property as may be lawfully bequeathed for charitable purposes to the treasurer for the time being of the Brompton Hospital for Consumption and Diseases of the Chest.—Mrs. Margaret Round, late of East-hill House, Colchester, £100 to the Colchester Hospital.—Mrs. Maria Newen, of 1, Hyde-park-terrace, £300 each to the

Digitized by Google

Brompton Hospital for Consumption; St. Mary's Hospital, Paddington; and the Cancer Hospital, Fulham.—Mr. John Marsden, late of Whitebanks, Chesterfield, Derby, £100 to the Chesterfield and North Derbyshire Hospital and Dispensary.—Mr. T. E. Jones, late of Whitefield House, Wilmslow, Chester, and of Manchester, £500 to the Montgomeryshire Infirmary at Newtown; £300 each to the Manchester Southern Hospital, Clifford-street, the Royal Eye Hospital, St. John's-street, Deansgate, Manchester, and the Home for Consumption and Diseases of the Throat, St. John's-street, Deansgate; and £200 to the Manchester Institution for Diseases of the Eye, Byrom-street; the residue of his property he gives to the Manchester Infirmary.—Mrs. Margaret William Tryon Cumberland, of Enham Lodge, Lillington, Warwickshire, £300 each to the North-West London Hospital and the Samaritan Free Hospital, Seymour-street, and £100 each to the Hospital for Women, Soho-square, and the Warneford Hospital, Leamington.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Derby Urban District.—Mr. Iliffe, in his annual report for 1886, draws a comparison between the state of the borough of Derby, as regards its appliances for improving public health and the prevention of disease, in 1877 and the year now reported on. The additions made to the security of the borough have been substantial, and they have, of course, not been made without a corresponding cost. But whereas the death-rate in 1877-81 was 21 per 1000, it has been 18·2 for the period 1882-86; the scarlet fever deaths per 1000 have fallen from 43·2 to 10·5, and the diarrhœa deaths from 37·2 to 32·0. Enteric fever has unfortunately had its downward course checked by the milk epidemic of 1884, a calamity for which it is held that the sanitary circumstances of the borough were not responsible. Unfortunately the experience of 1886 does not quite bear out this view. Derby was one of the districts inspected under the survey instituted by the Local Government Board in view of the cholera prevalence in Europe, and it is gratifying to note that Mr. Iliffe found material advantage from the co-operation of Mr. Spear in the task of improving such conditions as specially called for amendment. These related essentially to sewers, house drains, and midden privies; and, naturally enough, water supplies from local wells in such a place as Derby came under condemnation. Enteric fever was far too common in Derby in 1886, and, after a somewhat exhaustive consideration of the conditions leading to it, the conclusion is arrived at that it was mainly due to the contamination of the air by means of the deposits in midden privies. Under such circumstances any epidemic beginning with milk has its spread favoured. During the year a total of 336 cases of infectious diseases was notified; and the authority made final arrangements for erecting a new infectious hospital in the place of the wooden one heretofore serving almost exclusively for small-pox.

Wavertree Urban District.—Although the death-rate during 1886 was not excessive in Wavertree, having been 16·0 per 1000, yet the list of infectious diseases given by Dr. Harvey shows how much an infectious hospital is needed. Typhoid fever of a bad type occurred; scarlet fever often led to two, three, and four cases in the same house; and eleven cases of diphtheria occurred. Dr. Harvey recommends a small hospital in or near the district. Preferably, it should be in the district. There is too much tendency to profess to make use of hospitals in adjoining districts; whereas, as a matter of fact, the mere existence of the hospital elsewhere than in the district it is intended to serve often tends to prevent its use. Unless Wavertree can find such a hospital close to its own boundaries, it had better build a small one within its proper limits.

Runcorn Rural District.—Dr. Adams tabulates at length the instances of infectious disease occurring in his district, and the action taken with regard to each. An outbreak of typhoid fever at the Overton Grammar School House at one time caused anxiety, and led to a strong condemnation of the prevailing sanitary conditions. These were, however, fully remedied. Much of the action taken in this direction is materially facilitated by the early notification of disease which is given by an increasing number of medical practitioners. Great difficulties are experienced as to the water supply of Frodsham, and the blame for this is thrown on the central authority who, it is alleged, oppose every scheme submitted to them. The last attempt to deal with the subject has again been opposed on the ground that the supply in question was precarious in quantity and doubtful in quality—a decision in which Dr. Adams does not concur. In this he is supported by the county analyst, and by the result of experiments as to the quantity of water available. The death-rate for 1886 was 17·05 per 1000.

Friern Barnet Urban District.—The sewerage system does not appear to be as yet in working order in this district. When it is, it may be hoped that the complaints as to sewer emanations from ventilators, and as to which charcoal trays are admitted by Mr. Stott to be no proper remedy, will cease. Foul ditches should then also be done away with, the more so as at present they are associated with the prevalence of diphtheria and pneumonia. Some time since, Hornsey proposed to erect an infectious hospital close to this district. Opposition came from Friern Barnet, but now that the hospital is to be erected, joint action with Hornsey is suggested. The general death-rate for 1886 was 13·0 per 1000 living, but the zymotic rate was as high as 2·1, diarrhœa, due to defective sanitary conditions, being a cause of the excess.

Middlesex and Herts Combined Districts.—In his preliminary report on this combined district, Dr. Saunders refers to the fact that the repressive measures for the purification of rivers has been a conspicuous failure, and he is inclined to attribute this to the circumstance that attempted and actual legislation has been based on the assumption that trade pollutions were of the greatest consequence, and should be the first point of attack; whereas such pollutions are not nearly so serious as those which are brought about by the discharge of sewage into streams. And he next urges that, if our rivers are ever again to be clean, work must be done in their tributaries and in the sewer ditches which so often exist in rural and semi-rural districts. On the entire district the death-rate during 1886 was 16·4 per 1000, and the infantile deaths amounted to a rate of 116 under one year of age to every 1000 registered births. In the detailed descriptions of the several districts, attention is drawn to their most pressing sanitary wants. At times, as in Barnet, scavenging by the authority is urged; in other cases the need for keeping filth out of ditches the water of which is used for domestic purposes is dealt with. In the Watford rural district a serious epidemic of enteric fever took place in the London Orphan Asylum, the cause of the disease being set down as due to milk. In the Hendon rural district diphtheria at Little Stanmore again drew attention to the need for sewering the village; and at London Colney, in the St. Albans rural district, the school closets are reported as being in a scandalous state. This latter is a matter which should be brought under the notice of the Education Department, who can bring pecuniary considerations to bear upon school authorities. In some of the districts substantial improvements have been effected, some of these being of a permanent character; and we are glad to notice that the Albury Hospital, belonging to the Berkhampsted rural authority, has again served its intended purpose of preventing the spread of infection.

Epping Rural District.—The work done in connexion with infectious diseases is well set out in tables by Mr. Fowler, the action taken in each case being duly recorded. Diphtheria has been a serious cause of mischief in this district for some years past, and Mr. Fowler feels sure that it has not been due to any one specific cause, but that, having once been introduced, it has been spread by a variety of favouring insanitary conditions. Progress is fortunately being made as to water provision, and some good work has been done in the matter of drainage. The sanatorium has only been used for small-pox, no special demand having occurred for isolation in other cases. The death-rate for 1886 was 16·2 per 1000.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5787 births and 3621 deaths were registered during the week ending May 28th. The annual rate of mortality in these towns which had been 19·7 and 20·3 per 1000 in the preceding

Digitized by Google

two weeks, further rose last week to 20·4. During the first eight weeks of the current quarter the death-rate in these towns averaged 20·6 per 1000, and was 1·7 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 15·7 in Sunderland, 16·1 in Wolverhampton, 16·3 in Portsmouth, and 17·1 in Leicester. The rates in the other towns ranged upwards to 25·7 in Halifax, 26·0 in Preston, 29·5 in Huddersfield, and 32·3 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 500 and 532 in the preceding two weeks, were last week 522; they included 251 from measles, 143 from whooping-cough, 52 from scarlet fever, 31 from diarrhœa, 23 from diphtheria, 22 from "fever" (principally enteric), and not 1 from small-pox. No death from any of these zymotic diseases was registered during the week either in Wolverhampton or in Halifax; whereas they caused the highest death-rates in Salford, Manchester, and Norwich. The greatest mortality from measles occurred in Sheffield, Newcastle-upon-Tyne, Birkenhead, Salford, Manchester, and Norwich; from whooping-cough in Newcastle-upon-Tyne, Plymouth, Nottingham, and Preston; and from "fever" in Cardiff and Derby. No death from small-pox was registered either in London or in any of the twenty-seven large provincial towns. Only 4 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; no new case was admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 294 and 289 in the preceding two weeks, rose last week to 333, and exceeded the corrected average by 44. The causes of 79, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Preston, Norwich, and in three other smaller towns. The largest proportions of uncertified deaths were registered in Huddersfield, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·5 and 21·3 per 1000 in the preceding two weeks, rose to 22·6 in the week ending May 28th; this rate exceeded by 2·2 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 18·0 and 20·1 in Leith and Edinburgh, to 24·8 in Aberdeen, 25·9 in Perth, and 27·4 in Greenock. The 564 deaths in the eight towns last week showed an increase of 32 upon the number in the previous week, and included 43 which were referred to whooping-cough, 19 to measles, 10 to diarrhœa, 6 to scarlet fever, 4 to "fever" (principally enteric), and not one either to small-pox or diphtheria; in all, 82 deaths resulted from these principal zymotic diseases, against 78 and 72 in the preceding two weeks. These 82 deaths were equal to an annual rate of 3·3 per 1000, which exceeded by 0·4 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 31, 36, and 42 in the preceding three weeks, further rose last week to 43, of which 14 occurred in Glasgow, 7 in Edinburgh, 7 in Dundee, 5 in Greenock, 4 in Leith, and 4 in Perth. The 10 deaths attributed to diarrhœa also showed an increase upon recent weekly numbers, and exceeded by 2 the number in the corresponding week of last year. The fatal cases of measles, which had declined in the five previous weeks from 30 to 10, rose again last week to 19, of which 15 occurred in Glasgow and 3 in Aberdeen. The 6 deaths from scarlet fever corresponded with the number in the previous week, and included 2 in Glasgow, 2 in Edinburgh, and 2 in Aberdeen. Of the 4 deaths from "fever," 2 were returned in Glasgow and 2 in Aberdeen. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 106, 120, and 126 in the preceding three weeks, declined again last week to 109, but exceeded the number in the corresponding week of last year by 23. The causes of 71, or nearly 13 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 24·4 and 25·4 per 1000 in the preceding two weeks, declined again to 24·1 in the week ending May 28th. During the first eight weeks of the current quarter the death-rate in the city averaged 29·7 per 1000, the mean rate during the same period being but 18·6 in London and 19·6 in Edinburgh. The 163 deaths in Dublin last week showed a decline of 9 from the number in the previous week; they included 17 which were referred to measles, 3 to "fever" (typhus, enteric, or simple), 3 to whooping-cough, 2 to diphtheria, 2 to diarrhœa, and not one either to small-pox or to scarlet fever. Thus the deaths resulting from these principal zymotic diseases, which had been 19, 20, and 24 in the preceding three weeks, further rose last week to 27; they were equal to an annual rate of 4·0 per 1000, the rates from the same diseases being 2·9 in London and 2·2 in Edinburgh. The fatal cases of measles, which had been 9 and 8 in the previous two weeks, rose last week to 17, and exceeded the number in any previous week of this year. The deaths from both "fever," and whooping-cough showed, however, a decline from the numbers in the previous week. The deaths of infants and those of elderly persons were also fewer than those returned in the previous week. Three inquest cases and 3 deaths from violence were registered; and 46, or more than a quarter, of the deaths occurred in public institutions. The causes of 25, or more than 15 per cent., of the deaths registered during the week were not certified.

HEALTH OF STOCKHOLM.

In the Registrar-General's recently issued Annual Summary it was shown that in twenty-four of the largest European cities, having an estimated aggregate population of more than ten millions of persons, the mean death-rate during last year was equal to 27·2 per 1000, and exceeded the mean rate in the twenty-eight large English towns by no less than 6·3. It appears that the rates in these European cities ranged from 21·4 in Christiania, and 21·9 in Stockholm, to 33·0 in Prague, 35·0 in Marseilles, 37·8 in Buda-Pesth, and 38·0 in Trieste. The medical officer of health for the city of Stockholm has just issued a summary of the mortality statistics in 1886 for that city, and it may not be without interest to note a few figures bearing upon the mortality of one of the European cities showing for last year the lowest death-rates. The estimated population of Stockholm in the middle of last year was 213,762 persons. The birth-rate was 30·5 per 1000, and 2·7 below the mean rate in the twenty-eight English towns. More than 26 per cent. of the births were illegitimate, whereas the proportion in London does not exceed 4 per cent. With so high a rate of illegitimacy it is not surprising to find a rate of infant mortality out of all proportion to the death-rate at all ages. The return before us shows that the death-rate under one year was equal to 242 per 1000 living at this age; measured in another way, the deaths under one year were in the proportion of 218 per 1000 of the registered births, whereas the mean rate in the twenty-eight English towns did not exceed 169 per 1000. This high rate of infant mortality, in conjunction with the low death-rate at all ages, shows that the rate of mortality among adults in Stockholm was very low. The mortality from the principal zymotic diseases in this northern city was not on the whole high. No death from small-pox and only one from measles was registered, and the deaths from whooping-cough, scarlet fever, and enteric fever do not yield a high rate. The death-rates from diphtheria (including croup) and from diarrhœal diseases showed, however, a considerable excess, compared with the mean rates in the English towns. The aggregate deaths from the principal zymotic diseases gave a death-rate last year of 3·7, against 2·9 in the English towns, more than the whole excess in Stockholm being due to the greater fatality of diarrhœal diseases. Diseases of the respiratory organs and phthisis were somewhat less fatal in Stockholm last year than in London; while the death-rate from violence considerably exceeded the mean rate in the English towns. It is evident that, but for the terribly high rate of infant mortality, due to the markedly excessive proportion of illegitimacy, Stockholm would take a still higher place among the healthiest cities of Europe.

ON the 28th ult. the Princess of Wales, accompanied by the Prince of Wales and the Princesses Louise, Victoria, and Maud of Wales, opened the "Samuel Morley" memorial wing of the Deaconesses' Institution and Hospital at Tottenham.

Correspondence.

"Audi alteram partem."

THE COLLEGE OF SURGEONS' EXAMINATIONS.

To the Editors of THE LANCET.

SIRS,—In the concluding paragraph of my letter to you last week I made a reference to Mr. Heath's statement "that the standard of the examination has been lowered of late." Mr. Heath has written to me to say that he "can find nothing in his letter to justify" such a reference, and to assure me that he has "never said so," and that he does "not believe or wish it." Mr. Heath's *ipsissima verba* in his letter to you were: "A good deal has been done to improve the College of Surgeons' examination, with the object of gaining 'less uncertainty,' and even 'in the way of diminished stringency.'" I was under the impression that this expression "diminished stringency" implied that it was easier to pass the examination now than formerly, but Mr. Heath informs me that he referred to the practice of rejecting candidates for three months only, and he is anxious to have this stated in your columns. But this "diminished stringency" has what Mr. Heath calls the "set off"—that the examiners have now the power to refer candidates for nine or twelve months.

I am, Sirs, your obedient servant,

May 31st, 1887. A. PEARCE GOULD.

To the Editors of THE LANCET.

SIRS,—"Audi alteram partem" is your motto, and I should be glad if you could find space in your columns for a letter dealing with the large "referred list" from a candidates' point of view. An ounce of fact is worth a pound of theory, and I believe I can lay before you some facts which may throw a little light on the problem.

Of the candidates for the recent examination for the final Fellowship of the College of Surgeons, four—whom I know personally—came before the same examiner at one of the pathology tables. Three out of the four were referred—a result which will, I think, not be wondered at, when you consider how their examination at that table was conducted. No. 1 was examined for the whole twenty minutes on concussion and compression of the brain. No. 2 was questioned about syphilis of bone, and then about hip-joint disease. No. 3 was questioned the whole twenty minutes on fractured base of the skull, and No. 4 was asked precisely the same subject as No. 3. With regard to the actual questions asked of these candidates, I am able to reproduce only a few. No. 2 was asked, "How do you classify hip-joint disease?" Answer: "Arthritic, acetabular, and femoral." "Oh, nonsense," replied the examiner, "I never heard of such a foolish classification." The candidate then used the phrase "rarefactive osteitis." It was not accepted, the examiner remarking, "Why do you use such long words?" No. 4 candidate was questioned on the treatment of fractured base, and replied, "Perfect rest and slop diet." "What slops?" was the next question. "Milk, and beef-tea." "Yes; how much?" "Oh, four or five ounces every two or three hours." "That is, twelve meals of five ounces; why you would bring about the very mischief you are trying to avert—viz., meningitis."

Now, Sirs, these facts give rise to several questions. 1. I would ask, Is it fair that a candidate should be examined during the whole time at one table on one subject only? I submit that if the examiner found Nos. 3 and 4 weak on fractured base, he ought to have given them no marks (if he liked) for that subject, and then to have passed to other matters, to give them a chance of making up. I submit that every man has a weak point, and I assert it is unfair, when an examiner has found that weak point, that he should press the candidate on it to the total exclusion of all other subjects. 2. What is a candidate to do who is not allowed to use a classification of diseases found in what is admittedly the best text-book? And how can he be expected to clothe the science of to-day in any other garb than the ordinary scientific language of the day? Thirdly, with regard to the food for a patient with fractured base, why did the examiner purposely take the greatest frequency and the largest amount, and then bring out a total which is obviously absurd, and couple it with the remark quoted? It would seem as though he were bent on making the candidate appear as foolish as possible, and were trying to find his weakness instead of his strength. Making the worst possible case from a candidate's answer is *not* the proper way to examine.

This letter can, I am aware, have no possible influence on the fate of the three unfortunates; but I hope it may have some little influence in drawing attention to some stumbling-blocks in the path of the candidates which, by very little consideration on the part of the examiners, can be most easily removed.—I am, Sirs, your obedient servant,

London Hospital, May, 1887. FRED. J. SMITH.

To the Editors of THE LANCET.

SIRS,—Few of us can look back upon our student days without recalling personal instances of the "luck" of examinations. The subject is by no means new, but, on the contrary, is a source of perennial discussion and complaint, unfortunately with but little or no improvement. It seems to me that the method of selecting examiners from the ranks of successful practitioners is far from satisfactory; it is not always the most successful surgeon or most brilliant operator that makes the best examiner even in surgery, much less in anatomy or any allied branch. I can see no theoretical objection, at any rate, to the creation of a special class of examiners, who should spend the *whole* of their time in making examinations which should be more frequent and more thorough. It would then be possible for the examiners to go from school to school as a board of inspection, or even to conduct the primaries at the schools, so as to take account of the school records and inspect the actual work of the candidates. The latter, although examined more frequently by the College authorities, would save, at any rate, by a diminution of the class examinations, for which at present they get no credit at the College.

I am, Sirs, your obedient servant,

May 29th, 1887. M.D., M.R.C.S.

THE TREATMENT OF RINGWORM.

To the Editors of THE LANCET.

SIRS,—While most cordially agreeing with your article and the first part of Dr. Wilkinson's letter on the above subject, I cannot allow such a statement as he has made to go unchallenged by one who has also seen a little of this troublesome complaint. I refer to the following: "I make a bold assertion when I say that the disease is to be cured with one application"; and then the one application is said to be warmed glacial carbolic acid. Surely Dr. Wilkinson would not advise this treatment for all varieties of ringworm, both recent and chronic, and at any age: Ringworm constantly spreads over half or even two-thirds of the scalp—would Dr. Wilkinson use glacial carbolic acid to a large portion of the head or to a young child? I trust none of your readers will attempt such an experiment. Of course, carbolic acid is a well-known and good application for small places of recent ringworm if used with care; but I warn everyone against using it to a large surface, as it may cause unpleasant results and even scarring. Secondly, I cannot agree that one application of carbolic acid always, or generally, cures even recent ringworm. What would be the use—as Dr. Wilkinson suggests—of washing the head from time to time with a lotion of sulphurous acid (an excellent remedy) if the one application of carbolic had already destroyed all the fungus? I do not even suggest what is the best treatment for ringworm; but I do think that, when such a strong application as glacial carbolic acid is advised in your columns for such a common complaint, there should also be given full directions with regard to the size of the places, and the variety of the disease it is to be applied to; whether for recent or chronic ringworm, and if for chronic, whether for patches only, or for that most troublesome variety where there are no distinct bare places, but only stumps and groups of stumps. Such disseminated cases undoubtedly often remain uncured, in spite of the application of every known remedy, even for years. Each variety of this disease requires special treatment, and every treatment requires special instructions to be given with it. Applications that would be most proper and perhaps successful, if used to a

Digitized by Google

small patch of recent ringworm, would be both useless and unjustifiable if applied to a large surface of chronic ringworm or to the disseminated variety. I do not for a moment think I can cure ringworm more quickly than other men; but I do maintain that no end of cases are said to be cured when the disease is only in its most ordinary chronic form. Thus the doctor who certifies such cases to be well gets the credit of quickly curing ringworm; while those who refuse to certify if there are any diseased stumps remaining (and it is often most difficult to detect them) are thought not to be able so successfully to cope with the disease.

I cannot close without a few remarks upon your most excellent leading article, especially about the fact that "probably not 3 per cent." of hospital cases "are seen to their complete recovery," if it ever take place before puberty; and thus, to poor people, ringworm is "practically incurable in chronic stages." It is, as you remark, "of the first importance that the appearances in the more chronic forms of ringworm of the scalp should be readily recognised." There is no doubt whatever that children still suffering from this disease are frequently sent back both to public and private schools, even with medical certificates. After a long experience with regard to "certificates," I most fully endorse every word you say. Scarcely a week passes but I examine children for admission into private schools who have obtained certificates from medical men that they are free from ringworm, but who are still suffering from it in a most chronic form. Medical men of the highest professional standing often make the mistake of thinking ringworm is cured because the hair is growing freely on the affected places. There is no greater fallacy, for the most obstinate forms of this disease are those where the hair has grown again on the places, but where a few diseased stumps are still to be detected with a lens among the long hairs. The diagnosis of chronic ringworm is easy enough provided the medical man knows what to look for. My advice is to take no special notice of scurf, or whether the long hairs are growing firmly or not. Scurf may exist in patches and long hair may come out easily without ringworm being present; and, again, there may be severe chronic ringworm, and yet the long hairs on the patches may be quite firm and but little scurf may exist. The only diagnostic sign of any value is the presence, or the absence, of short broken-off diseased hairs called stumps. Ringworm rarely exists (except in the earliest stages) without a few broken-off hairs being visible; and certainly if there are any left the case is not cured, and the child may give the disease to others. Diseased stumps can generally be easily recognised, without the aid of the microscope, by noticing whether they break off on attempted epilation with a pair of forceps. If the stumps break off easily, leaving the root part behind in the follicle, there is but little doubt the case is one of ringworm; but if they come out with the roots entire and atrophied, it may be alopecia only: the microscope will settle the question.

I trust my long experience with this most troublesome and often intractable complaint will excuse these somewhat dogmatic remarks.—I am, Sirs, yours obediently,

Christ's Hospital, May 27th, 1887. ALDER SMITH.

ECONOMY IN THE WARDS.

To the Editors of THE LANCET.

SIRS,—The embarrassed condition of the funds of many hospitals, large and small, has led to all sorts of expedients for cutting down working expenses. Reform in our expenditure is becoming a favourite cry, and the shifts that many institutions have had, perforce, to resort to for some time past will become almost universal. There is one department in which I am sure great saving with a little care might be effected, and that is in connexion with the materials employed in antiseptic dressings. I was brought up at the feet of Gamaliel, so to speak, under a master who enforced the most rigid attention to every detail of Listerism, and woe betided the unfortunate dresser who omitted the smallest portion of the mystic ceremonies that were pursued at every bedside—such washings, and purgings, and scaldings, and sprayings, that one left the hospital daily with one's hair and skin impregnated with pungent odours, that were ineffaceable, and which were carried out to the theatre or dinner party, to the disgust of one's neighbour and the discomfort of oneself. On leaving London I became house surgeon to a country infirmary, where sepsis and poultices were the order of the day, and stinking stumps and fetid fractures rendered the wards almost unbearable. By the courtesy of the visiting staff I was allowed to act the part of the proverbial new broom, and certainly I did make a clean sweep of some of the smells. But when the bills came in for the gauze and the salicylic wool, the pounds-shillings-and-pence argument came into play with the board, who could not be made to understand the abnormal rise in their expenses. Our finances were limited, and I had to cast about to see in what direction a saving could be made. In fear and trembling, I first discarded the salicylic wool, substituting ordinary wadding, with no evil results; then, in a rash moment, I dispensed with the gauze, using instead Gamgee tissue, but without the wounds becoming septic; then the green "protective" went the way of the gauze, and a strip of carbolised oiled lint took its place; and, lastly, to the intense relief of my cracked and frozen fingers, I abandoned the spray. In fact, I gradually threw overboard every detail of Listerism as then practised, without the least bad result. Accidents of the most serious kind were frequent, it being a great railway centre; and, with compound fractures and tolerably frequent injuries requiring amputations, the test was ample and sufficient. I can unhesitatingly affirm that with a preliminary cleansing with a solution of carbolic or corrosive sublimate—of course, seeing that all the instruments were carefully cleaned—amputations were performed without the spray, the wound covered with iodoform powder, two or three thick pads of Gamgee tissue applied, outside that a quantity of oakum with a common calico roller, and the results were as uniformly satisfactory, and perhaps more so, than we had before under the more complex and certainly far more expensive system of prepared dressings; in fact, the simpler the dressing used the better the wounds seemed to do. I could quote a dozen cases of the most serious injuries where it was of vital importance to exclude suppuration, and where, with no more precaution than careful ablution and a sufficiency of soft absorbent material for dressing, primary union took place without a rise of temperature or the least discomfort to the patient. I found wood-wool by far the best dressing; its cost was very little, and pads of it covered with old linen formed an all-absorbing covering. The saving to the hospital was immense; indeed, we could not have afforded Listerian dressings as then practised. I am not advocating a return to the old days of water dressings, &c.; I firmly believe in antiseptic dressings, but I am perfectly sure that in our hospitals, daily and weekly, pounds are wasted in precautions that could be dispensed with. I have carried out the same treatment in private practice, and with the aid of iodoform, common lint, and tenax, have secured as good surgical results as we used to do with layer on layer of gauze, protectives, prepared wools, and special bandages. The hospital I speak of was not in a particularly healthy town, and our sanitary arrangements at one time were very bad. I know it is said that these results cannot be obtained in London. That that is erroneous is shown by some of the remarkable results achieved by men who use far less precautions than I did. Of course, where economy is no object (and I judge that there are very few hospitals where that could be said), or in those where a certain formula for wound dressing is obligatory, this economy of dressings is not to be expected; but I am sure that, were the actual cost of the materials employed in some of our wards during a year published, the figures would astonish the natives and foreigners alike. I am, Sirs, yours obediently,

June, 1887. J. G. MARSHALL, M.B. Cantab., M.R.C.S.

THE UTILITY OF DRUGS IN THE TREATMENT OF DISEASE.

To the Editors of THE LANCET.

SIRS,—In my green and salad days I, like many others, fell away from the scholastic belief in the utility of drugs, my apostasy to a great extent being due to a blind hero-worship and following of the investigations of Sir William Gull into the treatment of rheumatic fever. Does he still hold that the temperature in this fever cannot be lowered by salicine, and that it matters not to the result whether we use this valuable and certain antipyretic or give

Digitized by Google

mint-water? Must we now shut our eyes to the brilliant investigations of Brunton, Murrell, Frazer, Rutherford, Fothergill, Garrod, and a host of other recent writers, who without doubt show that this epoch in the history of practical medicine is more remarkable than any other for the unbounded and intelligent faith which scientific practitioners have in the utility of drugs in the treatment of disease? Is this warm bed to replace the surgery, and the warming-pan the hypodermic syringe? Everyone must admit that it is bad to give too much medicine, but what is worse than the trade mark on the prescription is the taint of empiricism. This, we hope, is passing away.

We now know how quinine cures neuralgia; how the bromides and chloral give sleep; how digitalis may be given so as to act on the kidney, strophanthus on the heart, amyl on certain peripheral blood areas, pilocarpine on the sweat glands, ergot on the arterioles of the lungs and uterus, &c. By the light of this more exact and fuller knowledge we have come, by slow but sure steps, to believe more implicitly than our fathers did in the action of remedies, and to ignore that panacea of ignorance, "expectancy." Our drugs are purer and more elementary, our prescriptions simpler and more scientific; and, with his hypodermic syringe and the long array of accredited alkaloids, the physician not only trusts more to the action of his remedies, but even dares to look forward to the time when his art will be based on scientific certainty. It may or may not be true (for it is still *sub judice*) that vaso-motor pathology justifies Sir William's beautiful theory of arterio-capillary fibrosis; but no one can deny that to vaso-motor therapeutics the general practitioner owes much of that calm faith and comfort at the bedside which is the aim of all true rational medicine. I am a general practitioner and dispense my own prescriptions, but I claim as high a platform as any consultant, be he who he may, who is content to ignore the light which is now flooding the field of therapeutics.

I am, Sirs, yours truly,

JAMES MORE, M.D.

Rothwell, Northamptonshire, May 29th, 1887.

THE CONTAGIOUS DISEASES ACTS IN INDIA.

To the Editors of THE LANCET.

SIRS,—In your issue of April 16th, page 792, you furnish a few remarks on this topic. The following facts emphasise in a remarkable degree the gist of your observations. Lock hospitals were introduced into India in 1866. Following their establishment the ratio of venereal disease in the army fell in a most remarkable manner, so much so that in 1873 the ratio per mille was 166·7; from then till 1877 the reduction was stationary. From 1877 to 1884 there appeared a steady increase in the ratio. This increase was made the reason for a determined onslaught on the existence of lock hospitals. It was chiefly in consequence of the discredit thrown on these institutions by the late Sanitary Commissioner with the Government of India, in his yearly statistical comments, that an experimental *reduction* in their number was ordered to take effect from the early part of 1885. It was then that we saw a truly marvellous increase in the venereal ratio. The excess of the 1885 rate over that of the preceding ten years was 192·0 per mille in the experimentally unprotected stations and 61·2 in the protected. The outcome of this experimentally closing of some of the lock hospitals in 1884-5 was that 130·8 per mille of the troops in cantonments where the lock hospital was closed contracted disease; the same, had the hospital been left open, would have escaped. So conclusive have these facts been that the Government of India have recently reopened all the lock hospitals which had been experimentally closed. It is probable that several causes exist for the relative increase of venereal disease in the Indo-European army apart from the closure of some lock hospitals. They appear to be—(1) a larger proportion of young men in the ranks; (2) a larger number of inexperienced men; (3) a lesser number of married men; (4) the increase of cold weather manœuvres; (5) the improved general health of the army, which is consistent with greater prevalence of sensual desire. Factors though these may be, their existence in no way vitiates the value of lock hospitals in the cantonments of India, but rather points to the necessity for the continued establishment of every precaution against venereal risks.

I am, Sirs, yours faithfully,

R. H. FIRTH, F.R.C.S. Eng.,
Surgeon, A.M.S.

Dagshai, May 2nd, 1887.

MR. WARRINGTON HAWARD'S CASES OF TRANSFUSION.

To the Editors of THE LANCET.

SIRS,—In a recent number of THE LANCET there appeared a communication from Mr. Warrington Haward, describing a method of transfusion which he had successfully employed in a case of hæmorrhage. Mr. Haward is evidently under a misapprehension as to the authorship of the method in question. In June, 1883, my friend, Mr. J. M. Cotterill, was good enough to perform transfusion on a patient of mine. This he did, with complete success, by the method which Mr. Haward has carefully described. Recognising the great merits which this method possesses, Mr. Cotterill strongly recommended it to other surgeons here, who, like himself, have since frequently performed it with marked success. While Mr. Annandale, Mr. John Duncan, and many other surgeons, here and elsewhere, who have since that date performed transfusion by Mr. Cotterill's method, have testified to its ease and safety, it is here well recognised that the credit is due to Mr. Cotterill for having brought the method under the favourable notice of the profession.

I am, Sirs, yours faithfully,

Edinburgh, May 24th, 1887. J. GRAHAM BROWN, M.D.

"A DOCTOR'S INCOME."

To the Editors of THE LANCET.

SIRS,—Dr. Paget Thurstan, in his letter of May 21st, suggests that county hospitals are one of the causes which contribute to the under-payment of the great mass of the medical profession. With this suggestion I entirely agree, but altogether dissent to his proposed remedy. Dr. Thurstan suggests that the general practitioner should be allowed to follow his cases to the hospital, and should receive for so doing exactly the same fees as he would have received for attending the patient at his own home. He forgets that a large proportion of the inmates of our hospitals are men, and that their families, deprived of the weekly wages, have great difficulty in providing the daily loaf, and would be quite unable to pay a doctor remunerative fees. Again, a large percentage of the patients are drawn from the surrounding villages, making it impossible for the country practitioner to drive often several miles to the neighbouring town, quite out of his usual round, to visit his patient in the hospital. It is not the in-patient departments of our county hospitals which injure the general practitioner, but the out-patient. In the present day the wives and daughters of small farmers, tradesmen, and well-to-do working men are most frequently allowed to attend the out-patient department without any questions being asked them. They have learnt and are teaching others to seek their county hospitals when they are well enough to make the journey, and to fall back on the country practitioner when they are too ill to leave their own homes. The remedy lies with the medical profession. Throughout the kingdom we have our medical societies, which meet at various intervals during the year. Why should not this question of hospital abuse and other similar questions affecting the profession at large be freely discussed at such meetings? If this were done, hospital physicians and surgeons would realise more fully than they yet have the gross injustice they inflict on the general practitioner by treating in their own out-patient rooms at the hospital, without making any kind of protest, patients who are well able to pay their own doctor moderate fees which would remunerate him for his services. I would further suggest that it would be a good opportunity, now that the subject is exciting a great deal of interest, to arrange for a discussion of the question at the next annual meeting of the British Medical Association in August.

I am, Sirs, yours truly,

WM. COLLIER, M.D.,
Hon. Physician, Radcliffe Infirmary, Oxford.

May 24th, 1887.

To the Editors of THE LANCET.

SIRS,—The happy idea of Dr. Paget Thurstan in bringing out so lucidly the inner life of the profession deserves all praise. But there is a point not brought out fully in his letters to THE LANCET. I mean the estimate put by the

Digitized by Google

public generally, and those classes who are addicted to the habit of visiting the out-patient rooms of hospitals particularly, upon the value of a doctor's services. A case occurs in my practice just now which deserves publication. Nearly three months ago I was called from dinner to assist a brother practitioner at a confinement by the husband of the patient, with the request that I would be prepared to administer chloroform, and *go at once*. The man seemed to resent the slightest delay, and scarcely allowed me to walk. It was a difficult case; great force was required to bring the head into the world with the aid of forceps, and the patient was under chloroform a long time. Last Thursday I called and reminded the husband that I had received no remuneration for my trouble and care, and requested him to send at his convenience *half a guinea*. Last evening I received a note to this effect: He did not acknowledge his liability. His wife had contracted with my friend to be attended for a guinea. He had fetched me at the request of their doctor, and I must look elsewhere for the money, adding, "*as for 10s. 6d., I should have thought 2s. 6d.*" The man is in good business and dresses well. Comment is not needed.—Very faithfully yours,

Kingsland-road, May 15th, 1887. GEO. LOCKE, M.R.C.S.

To the Editors of THE LANCET.

SIRS,—I have read Dr. Paget Thurstan's letter in your issue this week with interest, and I may add a suggestion to those already made—i.e., hospital physicians and surgeons attached to schools should be kept to their own special work (consultation), not only in the out-patient department but also in a private capacity. Loud outbursts of indignation are heard should some indigent general practitioner in a semi-starved condition, and driven to his wits end for the needful, issue to the denizens of his local slums a circular that he gives advice and medicine for 6*d.*, and competes with hospitals and chemists; but would anything be said should a consultant publish bulletins in *The Times* newspaper as to the state of an illustrious patient's health? Where is the line of advertising to be drawn? Under the present condition of things the medical profession is divided into two classes by the so-called higher and lower standard, which division is only with regard to fees, not practice, and is as wide as the gulf which separated Dives from Lazarus; for since there is no chance to rise from one status to the other except by the Chinese fallacy examination, interest, and money, why should we of the lower grade be robbed and ruled by an oligarchy who will not allow us to have a voice in the management of our own institutions? It is an old saying that "Charity begins at home," and while there are so many of our poorer brethren, it seems hard that all remuneration should go to the fortunate few. I am, Sirs, yours &c.,

May 23rd, 1887. M.R.C.S.E.

ACTION OF HYOSCINE ON THE EYE.

To the Editors of THE LANCET.

SIRS,—In an annotation in your issue of last week (May 28th) under the above heading, you mention some recent observations of Dr. O. Waller of Dorpat and others on this alkaloid. In THE LANCET of Dec. 4th, 1886, Mr. Tweedy, in an article entitled "On the Mydriatic Properties of Hydrobromate of Hyoscine," described some comparative experiments which I made for him between hyoscine and atropine, and in which all the facts noted by Dr. Waller had been observed. I am, Sirs, yours truly,

E. TREACHER COLLINS.

Royal London Ophthalmic Hospital, Moorfields, June 1st, 1887.

COLLEGIATE LECTURES.—Dr. Leonard Charles Woolridge commenced his course of three lectures on "Physiology of Nutrition" in the theatre of the Royal College of Surgeons on the 1st inst., and will be succeeded on the 8th inst. by Professor Christopher Heath, F.R.C.S. Eng., who will deliver three lectures on "Certain Diseases of the Jaws." The annual course of lectures will be brought to a close by Professor Henry Power, F.R.C.S. Eng., who will deliver three lectures on "The Relations of Ophthalmic Disease to Affections of the General System," commencing on June 17th. The lectures will commence at 4 P.M. precisely each day.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE EXHIBITION.

OUR Exhibition continues to increase in popular interest, and, notwithstanding gloomy and at times wet weather, the attendance is upon the whole very satisfactory. Yesterday, being Whit Monday, 45,000 passed in, making the total attendance since the opening on May 11th over 250,000. I should not omit to mention the model of the new infectious diseases hospital for the borough at Heaton, and now nearly complete. Last week a deputation from the Corporation of Nottingham, with Dr. Whitelegge, their medical officer of health, came over to see the hospital. They were received by the Sanitary Committee of our Corporation and the medical officer of health, Mr. H. E. Armstrong. They expressed themselves as being well rewarded for the trouble of the journey by the inspection of the building. Visitors to Newcastle should by no means omit to see the museum of the Natural History Society, which is a few steps from the Exhibition and on the same road. It is well known to be one of the best collections of natural history objects in the kingdom, and is frequently visited by foreigners. It has lately received some interesting additions, including a fine specimen of the echidna, porcupine ant-eater. This animal, which is peculiar to Australia, greatly resembles the hedgehog, but a little examination shows that it differs much from the spiny hystrix. The echidna is about a foot in length, and its body is covered with strong spines. The head consists of a long tapering snout, like the bill of a bird, from which it protrudes its long slimy tongue, and captures its food in the same manner as the great ant-eater. The limbs are short and strong, and the forelegs are armed with large and powerful claws, with which the animal burrows into the ground very rapidly. It is very apathetic, and tries to get out of sight quickly. It also rolls itself like a hedgehog, and in this way defends itself from attack. Another late addition, which, though not perhaps of great importance from a scientific point of view, possesses an interest peculiarly its own on account of its association with a name dear beyond Northumbria, Grace Horsley Darling. It is a collection of shells, crustacea, and birds' eggs, gathered on the Faroe Islands by Grace Darling and her father, and was bequeathed to the museum by her sister, Miss Thomasine Darling, who lately died at Bamburgh.

FEVER IN NEWCASTLE

At a late meeting of the Newcastle Sanitary Committee, the medical officer of health, Mr. H. E. Armstrong, reported that during the past fortnight there had been 1 case of small-pox, 7 of typhus fever, 14 of enteric fever, 1 of continued fever, 27 of scarlet fever, and 2 of diphtheria—a total of 52 cases. As regards the outbreak of typhus in the east end, it appears that there have been altogether 38 cases, all of which, with the exception of one, have been removed to the Fever Hospital. The solitary patient, who refused to go, caused a good deal of trouble by his obstinacy, and was the means of infecting two or three people who nursed him, each of whom had to be taken to the hospital.

Newcastle-on-Tyne, May 31st.

EDINBURGH.

(From our own Correspondent.)

THE VOLUNTEER MEDICAL SERVICE.

SUCH has been the success attending the formation of an ambulance corps amongst the students of the Edinburgh School, that it has now been decided to proceed further in this invaluable movement, and to raise a corresponding company from amongst the citizens of Edinburgh. The students' company, raised two years ago in response to the earnest appeals of Surgeon-Major Evatt, and commanded by Mr. C. W. Cathcart and Dr. Sims Woodhead, is constantly kept at its full strength; it has received official recognition and a definite status at the War Office, and it now takes part in all the movements carried out by the Volunteer regiments to which it is attached, in which both officers and privates

Digitized by Google

display much enthusiasm and devotion to the work they have undertaken. Although the new citizens' company will not possess the technical knowledge of the medical students that makes their corps so specially effective, it will probably be largely recruited from men who have taken some interest in the ambulance classes held in Edinburgh during the last three years; and starting on this basis some careful training in their work and frequent practice cannot fail to make the new corps a valuable addition to our Volunteer establishment.

THE ETIOLOGY OF SCARLATINA.

The announcement of Dr. Klein's discovery of a microbe that bears a causal relation to scarlatina has been received with great interest in Edinburgh; the more so since it has been known for some months that an elaborate research on the same subject was in progress towards completion in the laboratory of Professor Chiene. The matter was taken up by Dr. Jamieson, of the City Fever Hospital, early in the course of the recent epidemic in Edinburgh, and he and Dr. Edington, assistant to the Professor of Surgery, are reported to have isolated the *materies morbi* in the form of a small bacillus, whose life-history, physiological and pathogenic characteristics they have accurately defined. I hear that their paper has been for some weeks in the hands of the publisher, and that its immediate appearance is anticipated. There is a general curiosity here to know whether their results and those of Dr. Klein will be found to agree.

THE ROYAL INFIRMARY.

By the will of the late Mr. Archibald, of Edinburgh, a sum of £1000, free of all duties, has been left to the general funds of the Royal Infirmary.

ST. ANDREWS AMBULANCE ASSOCIATION.

A demonstration of ambulance work, under the auspices of the Scottish Association, is announced to take place in the Waverley market next week, and elaborate preparations are in course of completion, which should give it great interest in the eyes of the public. Recent cases of street accidents and of disasters in large manufactories have clearly shown the value of the work done by the Association. In particular, the Portobello police force have been of late complimented for their efficient treatment of a compound fracture that was found admirably treated on "first aid" principles on its arrival at the Royal Infirmary.

Edinburgh, May 31st.

DUBLIN.

(From our own Correspondent.)

THE QUEEN'S BIRTHDAY HONOURS.

LAST week I drew attention to the paucity of State honours doled out to the medical profession in this country by successive Governments. I now wish to add that, as regards the medical branch practising in Dublin, there is a leading physician whose claim ought in no way to be forgotten. I refer to Dr. William Moore, a physician of the highest eminence, who has filled numerous important positions in a manner not to be surpassed, and who is regarded with the greatest esteem by his professional brethren. Dr. Moore also holds the high position of Physician in Ordinary to Her Majesty in Ireland. These are considerations which ought to have due weight with Her Majesty's advisers.

HEALTH OF DUBLIN FOR 1886.

The death-rate in the city of Dublin for 1886 was 28·4 per 1000, while in 1885 it was 30·69, and in 1884 it was 29·96. The deaths due to zymotic diseases amounted to 823, or a decrease of 188 as contrasted with the year preceding. It appears from the annual report by Sir Charles Cameron, the efficient medical officer of health for Dublin, that one of the most serious factors in the Dublin mortality bills is pulmonary consumption. This malady caused 984 deaths in 1886, 988 in 1885, and 999 in 1884. It is remarkable that while the general and zymotic death-rates are declining, the mortality from constitutional diseases shows no decrease. It is satisfactory to learn that a substantial reduction in the death-rate of Dublin has taken place within the last six years, and the reduction has been mainly in the mortality caused by infectious diseases—those which sanitation can most effectually deal with. With our present underfed, poorly-clothed, and badly-housed working population, we can hardly expect that the death-rate from all causes can be reduced to that of the prosperous cities of England. It is, however, some consolation to reflect that in 1886 we had the lowest mortality since registration of deaths commenced in Dublin, that our zymotic death-rate was well below the average in English towns, and that our general mortality was less than the average general mortality of the chief continental cities. The mortality due to constitutional diseases is, however, still excessive in Dublin; but the measures for lessening it must be sought for in the domain of political economy as well as in that of hygeia. As Sir Charles Cameron points out, just in proportion as the people are well fed, well clad, and well lodged, will they, by reason of their higher vitality, be able to resist the assaults of both constitutional and infective diseases.

M. PASTEUR'S TREATMENT OF HYDROPHOBIA.

The guardians of Thurles Union some time since sent to Paris a youth named Hayden, who had been bitten by a mad dog, to undergo treatment by M. Pasteur. Attenuated virus was daily injected on twenty-nine occasions, and Hayden was to leave Paris on a certain day for home. On April 19th he arrived at the institute, and on May 17th arrangements were made that he should return to Ireland. The day after he left the institute the boy went out for a walk, and on his return to his lodgings he complained of pain in the stomach, which was followed by vomiting and convulsions, death taking place thirty-six hours afterwards from hydrophobia.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

A meeting of the Fellows is to be held to-day (Saturday), to receive the annual report of the Council, when the following motion by Sir Charles A. Cameron will be under consideration:—"That the College regret the failure of the attempt to unite the Colleges of Physicians and Surgeons and the Apothecaries' Hall for the purpose of holding examinations. The College is of opinion that a fresh attempt to effect this tripartite combination should be now made—the Medical Council having recognised the Apothecaries' Hall as a medical corporation; and should such an attempt again fail, the College considers that the Council should, if possible, form a combination with the Apothecaries' Hall."

Dublin, May 31st.

PARIS.

(From our own Correspondent.)

CURABILITY OF LOCOMOTOR ATAXIA.

M. BABINSKI related at the Society of Biology the cases of several ataxic patients who had been cured. One of these patients, after having suffered for ten years from violent lightning pains, which prevented him from undertaking any kind of employment, at least three times a week, has been cured for the last five years. In another case the symptoms set in with violent pains, disseminated anæsthesia, and urinary and fæcal incontinence. During ten years the disease steadily increased, then grew gradually less severe, and for the last four years the patient has been quite well. The third observation is, however, the most interesting, inasmuch as the anatomical proof of the recovery from previous disease was obtained. The patient was a woman whose symptoms comprised grey degeneration of the optic nerve, lightning pains, gastric crises, and abolition of reflexes; no incoördination. M. Charcot has frequently shown this woman at his lectures as a typical example of tabes fruste. The pains, after existing for twenty-five years, completely disappeared. The patient died five years later of pneumonia. The post-mortem examination of the cord showed unmistakable lesions of locomotor ataxy; but, with the exception of blindness, recovery had taken place from all their consequences. Dr. Brown-Séquard said that he had long been convinced of the possibility of such recoveries, but he was happy to find the evidence brought forward by a school opposed to his doctrines. It proved conclusively, as he had always taught, that lesions of the nervous centres do not give rise to symptoms, as destructive lesions

Digitized by Google

)ut by an inhibitory action on other parts. In reply o a question, it was stated that one of the patients had been to Lamalou ten years in succession, and had always returned improved. The others had been treated by revulsives. Dr. Brown-Séquard observed that it was important o apply revulsive treatment, not to the back, as was generally done, but to the lower extremities. The cord is acted upon in this way by all the sensory nerves, and the effect greatly increased. He quoted the case of a medical man, who was cured of locomotor ataxy by circular blisters around the leg and thigh. The same treatment is also of the greatest value in epilepsy with aura.

TREATMENT OF INTESTINAL OBSTRUCTION.

An interesting discussion has been provoked at the Société de Chirurgie by a paper by Professor Verneuil on the Treatment of Intestinal Obstruction. The practical conclusions would seem to be that if the course of events does not give rise to immediate anxiety, medicinal means, such as purgatives, enemata, rectal douches, and electricity, should be tried in the first instance. These means should not, however, be relied upon too long, as thereby time is lost and they exhaust the bowel. M. Marc Sée's case of recovery by the use of rectal douches forty-five days after the onset of the symptoms is entirely exceptional. A surgical operation being decided upon, two choices are open, each having its special indications—laparotomy or artificial anus. When the diagnosis is easy and the obstruction is known to result from chronic disease, such as cancer, there is no question as to the treatment to be preferred. An artificial anus must be made, either on the right, as advised by M. Le Dentu, or at the iliac flexure, as counselled by Professor Verneuil. When the symptoms have set in acutely and there is good reason to believe that they depend upon an obstacle that can be removed by reasonable exploration, laparotomy should be resorted to. In a great many instances of acute and subacute obstruction of the bowels the Society recognised that a diagnosis was impossible, notwithstanding the opinion of M. Desprès that it ought to be made ninety-nine times out of a hundred. Opinions were divided as to the best treatment. M. Verneuil would treat symptoms and make an artificial anus; MM. Trélat and Le Fort prefer laparotomy; and if a short exploration prove fruitless, the operation should be transformed into enterotomy.

THE INSTITUT PASTEUR.

It is said that M. Pasteur has once more modified his method of anti-rabic inoculations. For simple wounds he has returned to the first system of mild attenuated virus. For bites about the face and head, and severe bites about the body, more virulent medullæ are used, but these do not attain the virulence indicated by M. Pasteur in his last communication. The last three deaths are: Ph. Hydram, aged fifty-six, bitten on October 5th, and treated from the 10th to the 21st of the same month; died on April 21st of rabies. J. B. Gachet, twenty-five years of age, bitten on April 4th, treated from the 10th to the 20th, and died on May 2nd. J. Hayden, aged eight, bitten on April 16th, treated from April 22nd to May 15th; died on the 18th.

THE BURNING OF THE OPÉRA COMIQUE.

It is to be hoped that the catastrophe at the Opéra Comique will lead to some practical improvements in the Paris theatres. This is a subject which comes up every time a large and fatal fire takes place; but like the periodical typhoid fever scare, it is forgotten as soon as the balls for the benefit of the sufferers are over, and the persons who fatten upon charity organisations have closed the accounts of the transaction. It is somewhat ghastly that one of the official medical advisers to the administration of the Opéra Comique should be the Professor of Public Health at the School of Medicine. Perhaps this calamity will prompt him to ascertain whether there are any other duties attached to the post than those which consist in applauding the actors once or twice a month, and occasionally prescribing orange-flower water for a lady of the troupe suffering from her *nerfs*. The papers publish a note upon an examination of the blood of the victims, said to have been made at the Morgue by M. Brouardel, and which would show that death occurred in three different ways—(1) from fright; (2) from asphyxia by carbonic acid; (3) by asphyxia from carbonic oxide. Apparently no one was crushed to death, which is scarcely likely.

HYPNOTISM IN THE PARIS HOSPITALS.

Although hypnotism is not practised here on as large a scale as at Nancy, there are some cases which medical men visiting Paris should see. MM. Charcot, Luys, Dumontpallier, and Mesnet have the most interesting subjects at the present moment, the last-named gentleman having a woman under his care in the Salle St. Martine at the Hôtel Dieu who was confined without consciousness during the hypnotic sleep.

Paris, June 2nd.

EGYPT.

(From our own Correspondent.)

RABIES AND HYDROPHOBIA.

THESE diseases are almost unknown in Egypt, but the fact that the police in Cairo have during the last eight months destroyed 5233 street dogs has been construed by some lay journals into a belief that a large number of persons had been bitten by rabid dogs, and had died of hydrophobia. Pariah dogs, which act as scavengers in the native quarters of the town, are destroyed in considerable numbers every year, and the extra energy of the police during the past winter was only caused by various complaints of householders who were kept awake at night by sleepless mongrels, which had become far too numerous. Griesinger, Larrey, Watson, and many other writers say that rabies and hydrophobia are quite unknown in Egypt, but Fleming notices that travellers have asserted the presence of rabies here. Most of the cases reported during the last five years have been very doubtful, though some have been observed by European doctors in Cairo and Alexandria. An argument employed to prove the existence of the disease is that the Bedouins have a well-known remedy for bites, consisting of a hard pointed root, which certain of their "medicine men" thrust into the fire and then cauterise with it the wounds of the bitten.

CASE 1.—In December, 1882, a Swiss doctor near Cairo was called hurriedly to see an Egyptian gardener, whom he found lying on the ground, much excited, foaming at the mouth, and being held by three men. He had occasional convulsions, during the intervals of which he bit the doctor in the back of the hand while his pulse was being felt, and within half an hour he died, and was buried without a necropsy. The doctor then heard that twenty-eight days previously the man had been bitten in the forehead by a cat, and for the last three days had been unable to drink. Until three days before he had been quite well, though formerly troubled with asthma. The cat was killed after it had bitten a soldier through his trousers, and its body was not examined. The doctor and the soldier have never suffered from their bites. The man apparently bit the doctor to show his hatred of a Christian. In May, 1886, twelve women and children were bitten by a wolf in the early morning near Cherbin. The wolf was seen standing over a small child gnawing at its head, and the child died fifteen days after from its injuries. It was proposed by two native inspectors to return this case as hydrophobia, but their opinion was rightly overruled by an English veterinary surgeon. The other eleven bitten people recovered satisfactorily.

CASE 2.—Again, in May, 1886, a cat in Upper Egypt bit two natives, who were sent to Paris to be treated by M. Pasteur. This case rests on the evidence of M. Piot, an able French veterinary surgeon, who disinterred the cat two days after burial and inoculated two rabbits from it. The two rabbits died from either rabies or septicæmia.

CASE 3.—In August, 1886, an authentic case of dumb rabies was certified by English veterinary surgeons as occurring in a suburb of Cairo in a terrier belonging to the Army of Occupation. The terrier was kept under observation, but unfortunately escaped one night, and was found dead in the desert the next day.

CASE 4.—In October, 1886, three Syrian children in Cairo were bitten by a dog, of which nothing is known. Six weeks later, Dr. Grant was called to see one of these children, aged six, who had a scar from the bite at one angle of his mouth, and was then complaining of fever and of a burning sensation in the throat. The medicine prescribed could not be swallowed, and the child passed a

Digitized by Google

very excited night, leaping incessantly in and out of bed, and refusing to drink a chloral draught. Early next morning the boy was seen, with a frightened harassed air, sitting at the far corner of a large bed, like a monkey, and again complaining of his burning throat, his temperature being still raised. He trembled all over when water was called for, but had no convulsion until it was brought near him. He was thirsty, but absolutely refused to try to drink, though after some shuddering he could extend two fingers at arm's length, touch the water, and then apply his fingers to his tongue. An attempt at hypodermic injection induced so many convulsions that it was abandoned. The same night the boy was seen again by Dr. Grant, two colleagues, and a French veterinary surgeon. The boy was then extremely excited, and could only be kept on the bed if his mother sat upon it with him. When a light was brought he dodged round his mother to avoid it. A touch of the hand induced convulsions, and each of the doctors singly tried, but failed, to inject morphia. The boy died the following morning, but there was no necropsy. The other two children were then sent to M. Pasteur for treatment, and have remained well.

CASE 5.—In January, 1887, the dog of an Austrian woman bit her in the nose, and she has undergone M. Pasteur's treatment with success. The dog died presumably of rabies. From the pons Varolii of the dog's brain two rabbits were inoculated in the eyes by Mr. Littlewood, and cerebro-spinal fluid was further injected under the skin of their thighs. Fourteen days after one rabbit died without symptoms of rabies; the lungs were very congested, but there were no other important facts noted at the necropsy. The second rabbit on the fifteenth day suffered from marked photophobia, hiding itself from the light, facial paralysis, and convulsions of the whole body. Death occurred six hours after these symptoms were first seen. All the organs were found deeply congested and the bladder was full of urine. Mr. Littlewood believes that this second rabbit died of inoculated rabies. Unfortunately, no thermometrical observations were made to test the rapid loss of heat which seems pathognomonic of the Pasteurian inoculations.

CASE 6.—On Feb. 15th, 1887, an Egyptian was bitten by a wolf, of which nothing is known, in a village near Tantah. Thirty-seven days later, on March 24th, a Greek doctor certified that this man had died of hydrophobia. He complained of headache and was delirious, and refused to drink for two days before death, and on the day preceding death he fell down some steps, but without injuring his head. At the necropsy, the lungs were found gorged with blood and inflammation in the membranes of the brain. The larynx, pharynx, intestines, and kidneys were normal. From the brain of this man two rabbits were inoculated, as in the last case. They were fed on bran instead of clover, and both became thin and wasted, one of them dying of starvation. At the necropsy great atrophy was seen, but no congestion of the organs. The second rabbit was then returned to a clover diet, at once improved in health, and is now perfectly well.

The Sanitary Department now does all that it can to encourage bitten people to bring the dogs to be watched, instead of their being at once killed. Since October last more than a dozen dogs have been kept under observation for periods exceeding one week, and, so far, in every case the dogs have proved to be healthy. The above record of six cases, including doubtful ones, represents all the returns of hydrophobia in Egypt during the last twenty years.

RELAPSING FEVER.

Occasional small outbreaks of this fever have been reported this year by native doctors in Lower Egypt, but they have not been verified by any skilled observer. During March and April there were eight cases reported from an overcrowded prison at Damanhour, of which one died.

ELEPHANTIASIS.

M. Innes, Curator of Museums at the Medical School, believes that he has recently discovered a bacillus which is special to the erysipelatous elephantiasis of the Arabs. The bacillus, coloured blue by methylene and not affected by the Ehrlich method for colouring the leprosy bacillus, occupies in masses the connective tissue which forms the scrotal or other tumour. Under a microscope of 1200 diameters it appears straight, slightly swollen at its middle, and tapering at both ends. But this investigation will require much subsequent confirmation. The eggs of the filaria sanguinis hominis are rarely found in cases [illegible]hantiasis in Egypt.

BLIND AND DEAF SCHOOL IN CAIRO.

This school is deserving of praise because it is entirely under native direction, and because the houses and all their contents are scrupulously clean. Of the blind, there are now thirty-one boys and twelve girls, who learn reading, writing, arithmetic and geography, besides mat and chair making, silk weaving and carpentering. Most of the children were suffering from extreme corneal opacities after granular lids. On the deaf and dumb side there are nine boys and eight girls being taught by deaf teachers.

Cairo, May 21st.

MEDICINE AMONG THE MOORS.

(From a Correspondent.)

THE mantle of Avincenna or Adul Axis has not fallen on the shoulders of the modern Moorish doctor. The leaders of scientific research and progress during the dark ages have not advanced, but, on the contrary, they have materially retrograded. Superstitions have gained ground; scientific precepts have been forgotten; astrology is still associated with medicine; and for the little skill occasionally displayed, and a few good local remedies, we have, as an offset, an appalling prevalence of crude ignorance and savage superstition that can scarcely be exceeded, even in the most barbarous parts of the world. The Moorish "medicine man"—we can hardly call him doctor—certainly displays some skill in couching for cataract. He has also an original method of curing irritation of the eyes due to the presence of foreign bodies: with much skill he passes his tongue over the open eye of the patient, and thus, without irritating, removes the sand, grit, &c. For cupping, the Moor also makes good use of his mouth: a cow's horn is placed over the part, and from a hole at the point of the horn the operator sucks out the blood &c. But the Moor who ventures on such treatment will, with equal confidence, prescribe gold dust, or the scrapings from the horn of a rhinoceros, as an emmenagogue; and will give an idle man ants to eat, or suggest that a coward should try and procure for his meal a little lion's flesh. The fumes of the burning bodies of animals are supposed to be a good remedy for anæmia.

In such matters the Jews of Barbary, who form an important section of the population of Morocco, are as superstitious as the Moors with whom they live. Though naturally a gifted and highly intelligent race, the Jew is as prone as the Moor to attribute his ailments to the intervention of evil spirits. If a man is ill, it is customary to place a dagger under his pillar so as to intimidate the evil one. At the birth of a child, the father, if he is a Jew, takes a big and sharp sword with which he cuts and slashes about the room in the hope of destroying the evil spirits that may be seeking to retard his wife's convalescence or that menace the child's future. Should this be considered insufficient, the pots and pans are violently struck together, and everyone helps to make an alarming noise under the impression that it will frighten illness away. This disturbing method of warding off the dangers of the situation is continued till the seventh day, or the time of circumcision. When, on the other hand, there is no family, the empiric practitioners of this country have propagated the very convenient belief that a sapphire, an emerald, a pearl, and some coral ground into powder and mixed with alcohol, constitutes an effective drug for the cure of barrenness. It is needless to say that the patient is not allowed to grind up the precious stones herself, but must confide them to the care of her medical adviser.

Nevertheless, by the side of these absurdities there are some good remedies employed. The Moors, for instance, use the actual cautery, and, by freely applying red-hot irons to the skin, often succeed where in more civilised practice the mustard poultice or the blister fails. Excellent syrups are made for coughs and colds by simply boiling figs, dates, and raisins; while the huge, thick, prickly pear leaf, when cut in two and heated, is a very good substitute for the linseed poultice. The same leaf, put on a plate and covered with brown sugar, will make a very good cough lozenge when the sap oozes out and mixes with the sugar. For fracture, the limb is dressed with splinters and tow soaked in honey. The honey, of course, attracts a multitude of flies, and thus

Digitized by Google

augments the annoyance the patient has to endure; but, nevertheless, some skill is sometimes shown in the dressing of wounds. A plant, vulgarly known among Europeans in Morocco as the "donkey's fig," and called by the Arabs the "Feghouz elhmir," is much used in jaundice. Cut in two and held to the nose, it will cause a violent irritation of the nasal mucous membrane, followed by a copious discharge, which it is thought relieves jaundice.

The henna sold for staining the heels of the foot and the nails of the hand a bright orange red, which among Arab women is a favourite method of ornamentation, is also employed as an astringent for eruptions on the heads of infants. The root of the wild grenade, or assouak, is effective as an astringent for the lips and gums, and it imparts a marvellous whiteness to the teeth. For the purposes of a purgative the Arabs generally resort to a decoction of senna and honey. The "khol," or sulphate of carbon, with which the women black their eyelids, is used not only from motives of coquetry, but to help to cure slight ophthalmia. This latter reason is said to account for the fact that men also occasionally paint their eyes. It is strange, however, that this painting is especially prevalent on festive days, notably during weddings. Is it only when their powers of vision are more or less affected that Moors make up their minds to incur the pleasures and dangers of matrimony? Such a supposition is not a complimentary reflection on the personal appearance of Moorish women; but, nevertheless, men even in Morocco do not care to admit that they paint merely to satisfy their personal vanity.

Undoubtedly the fatalist theory of the Mahomedan religion is chiefly responsible for the deplorable ignorance prevalent on all medical matters. The Moor considers it more or less wicked to avail himself of the science of the Christian. For instance, at Tangier the Minister of Foreign Affairs has been urged over and over again to have some false teeth. He, however, invariably replies that, if God has thought fit to deprive him of his teeth, it is not for him to set at defiance the will of the Almighty by putting in false teeth. In the same manner, the actual Governor or Bashaw of the Province of Tangier obstinately refuses to avail himself of the advice of any European practitioner, though his health is in a very precarious condition. This fatalistic resignation has been combated with much energy by the Bashaw's European friends, as they greatly value his life, and fear it will be difficult to find a successor equally energetic in putting down abuses. Nevertheless, the Moors will very rarely follow the advice of European doctors. With the exception of a few rough remedies to relieve pain, they generally prefer to trust in Allah, or else resort to necromantic practices.

THE SERVICES.

Deputy Surgeon-General Jas. H. Thornton, C.B., I.M.S., has been awarded an Indian good-service pension from Dec. 8th, 1886, in the room of Col. Sir F. B. Norman, K.C.B., Bengal Staff Corps.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Surgeon Robert Arthur Simpson, M.B., has been allowed to withdraw from Her Majesty's Naval Service with a gratuity.

The following appointments have been made:—Fleet Surgeon William Graham to the *Unicorn;* Fleet Surgeon Henry A. Clone, to the *Durham* (to date from May 28th); Staff Surgeon Matthew F. Ryan, to the *Tamar;* Staff Surgeon Henry Beaumont, to the *Invincible* (to date from May 28th); Staff Surgeon Michael Roman, to the *Rover* (to date from May 28th); Surgeon Alexander N. French, to the *Agincourt;* Surgeon James Rogers to the *Pembroke;* and Surgeon Charles F. Newland, to the *Invincible* (to date from June 2nd).

ROYAL NAVAL ARTILLERY VOLUNTEERS (London Brigade). Alex. Stewart Brown, to be Surgeon (to date from May 28th, 1887).

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—The thirty-fifth anniversary festival of this institution was held on the 25th ult., the Marquis of Ripon presiding. Since the establishment of the hospital in 1854, 400,000 out-patients and 24,000 in-patients have been treated, the numbers last year being 15,000 and 1100 respectively. A list of subscriptions and donations amounting to upwards of £1500 was during the evening announced by the secretary.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 26th ult. the following degrees were conferred;—

DOCTOR OF MEDICINE.—Henry Lewis Jones, Gonville and Caius.

BACHELOR OF SURGERY.—James Kerr, St. John's.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At recent meetings of the Court of Examiners the following obtained the Fellowship of the College:—

Thomas Higgins. | John H. Scott.

SOCIETY OF APOTHECARIES.—The following gentlemen, having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates entitling them to practise as Licentiates of the Society on May 26th:—

Dean, Henry Percy, Anson-road, Tufnell-park.
De Renzi, Arthur Castriot, The Chaplain's House, H.M. Prison, Wandsworth.
Clark, Calvin Worcester Day, Regent-square.
Harris, Worsley John, Bennett-park, Blackheath.
Johnson, Harold Jossé, Bishopsgate-street.
Mausell, H. Rosser, Lynchmere, Maberley-road, Upper Norwood.
Read, Henry George, Finsbury-square.
Servaes, Francis Charles, Northern Hospital, Liverpool.
Thomas, John Lewis, Brynmowr, Breconshire.
White, Charles Percival, Furnival's-inn, Holborn.

VACCINATION GRANT.—Mr. Julius Cæsar, Minster in Sheppey, has received the Government grant for successful vaccination (first time).

THE War Department has granted a piece of land at Woolwich for the erection of a hospital in commemoration of the Queen's Jubilee.

ON the 26th ult. the Metropolitan Counties Branch of the British Medical Association held a highly successful conversazione at the South Kensington Museum.

THE Danish corvette *Dagmar*, which has been on a cruise in the North Sea with cadets, has put into Sheerness Harbour with three cases of diphtheria on board. The patients were admitted to Melville Hospital, Chatham.

THE SALE OF POISONS.—Cases are occurring almost every week which show the urgent need of reform in the Sale of Poisons Act, and of the greater stringency in the enforcement of the provisions already in existence.

BEQUESTS.—The late Mr. G. Woods Maunsell has left £50 to the Adelaide Hospital, Dublin. Mr. Wm. Magrath has bequeathed £500 to each of the following institutions—viz., Mater Misericordiæ, Vincent's, and Jervis-street Hospitals.

EAST LONDON HOSPITAL, SHADWELL.—The annual court of governors of this institution was held on the 31st ult., when it was reported that 16,012 patients had been attended during the year, making 178,644 since the opening of the institution in 1868. The receipts for the past year amounted to £7053, against £6699 during the preceding year, and the total expenditure was £6803.

ASSOCIATION OF PUBLIC SANITARY INSPECTORS.—On the 28th ult. the second provincial conference of the members of this Association was held at Eastbourne. Papers on health, drainage, and sanitary questions generally were read and discussed, amongst those present being Dr. A. Carpenter, Mr. G. A. Wallis, Mr. Toms, and Mr. Walter Grant. After the conference the Association visited the places of interest in the town.

PRESENTATIONS.—Dr. Lawton Roberts has been presented with a copy of Keith Johnston's "Royal Atlas of Modern Geography," a case containing an inkstand, a pen-stand, and a pair of candlesticks by the men employed at the Plaskynaston Collieries, in recognition of his services as medical officer, and with an electro-plated tea and coffee service by the members of the ambulance classes for his services as instructor.——Dr. Davidson of Wartle has, on the occasion of his golden wedding, been presented with a marble timepiece and a purse of 100 sovereigns as a mark of the esteem and respect in which he is held throughout

Digitized by Google

the district.——Mr. John Blackburn of Barnsley has been presented with a silver drinking-cup by the police of the Staincross Division of the West Riding of Yorkshire, in recognition of his services as teacher of the ambulance class.—Mr. Charles Sanders has been presented by the members of his ambulance class with a handsome edition of the works of Charles Dickens.—Mr. W. Jenner Reid has, on the occasion of his leaving Esher, been presented with an illuminated address and a purse of over fifty sovereigns by the inhabitants of that village, as a token of their regard and regret at his departure.—On the 28th ult. Mr. Jordan Lloyd was presented, as a wedding present, with a cheese dish and a butter cooler by the sisters and nurses of the Birmingham Queen's Hospital, and also by the past and present resident officers of the institution, who had been associated with him in the work of the hospital, with a silver salver and an illuminated address.

THE Jubilee celebration of the National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen-square, will take place on July 7th, when the Duchess of Albany will open the wards hitherto unoccupied, including the ward for children which bears her Royal Highness's name, thus raising the total number of available beds to 180. A show of roses and other flowers by Paul and Son, of Waltham-cross, with additional attractions, will be provided.

ON the 27th ult. an alarming and destructive fire occurred at the private asylum known as Brooke House, Clapton High-road. One of the inmates was, unfortunately, burned to death. An inquest was held on the body of the deceased, and the jury, who returned an open verdict, appended a rider to their verdict complimenting Dr. Adams, the proprietor of the asylum, and the members of his staff for the promptitude they had displayed in endeavouring to extinguish the flames.

LONDON TEMPERANCE HOSPITAL.—The annual public meeting of the supporters of this institution was held on the 27th ult., under the presidency of the Rev. Canon Ellison. During the twelve months ending April 30th, the number of in-patients treated was 737, the deaths amounting to 57, or 8·4 per cent. During the 14 years in which the hospital has been in existence more than 4000 in- and 26,000 out-patients have been received. The income for the year was £5075, leaving after payment of expenses a balance in hand of £38. The debt on the hospital amounts to £6500, and until this is paid it is not considered prudent to open to the public the whole of the 120 beds which the building contains, of which 60 only are at present in use.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following Examiners have been elected for the ensuing year:—Anatomy: J. Barton, F. A. Nixon, W. T. Stoker, R. L. Swan. Surgery: C. B. Ball, E. S. O'Grady, W. Thomson, A. F. Tobin. Physiology and Histology: E. D. Mapother, J. A. Scott. Medicine and Therapeutics: M. A. Boyd, R. A. Hayes. Chemistry, Physics, and Medical Jurisprudence: J. D. Pratt, S. H. Webb. Midwifery and Gynæcology: J. J. Cranny, S. R. Mason. Ophthalmology: A. H. Benson, H. A. Swanzy. Diploma in Midwifery: J. J. Cranny, H. Croly, W. Roe. Public Health: E. Flinn, E. Lapper, W. Parry, H. Tweedy. Preliminary Education: F. Davys, R. Morton, H. C. Tweedy.

INSTRUCTION TO VOLUNTEER MEDICAL OFFICERS.—On Wednesday, May 25th, the last of a course of six lectures to Volunteer medical officers was delivered by Dr. Walter Pearce in the Parkes Museum. Dr. Farquharson, M.P., occupied the chair, and there was a large attendance of medical officers and of members of the Volunteer Ambulance Department. Surgeon Stewart, M.D., Middlesex Yeomanry Cavalry, moved a vote of thanks to the chairman, which was seconded by Surgeon Stokes, London Rifle Brigade. Dr. Farquharson, in reply, said that he took much interest in the subject of the lecture, especially in the rations of the soldier. He hoped that ample opportunity would be given for the discussion of the Army Medical Estimates in the House of Commons, and that he should be ready to put forward the grievances of the Volunteer regimental surgeons, and their deprivation of pay and allowances while under instruction at the Medical Staff Depôt at Aldershot.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

ANCOATS HOSPITAL, Manchester.—Junior Visiting Surgeon. Salary £80 per annum, with board and laundry service.

BIGGLESWADE UNION, BEDFORD.—District Medical Officer. Salary £120, with extra medical fees, as allowed by the Local Government Board.—Medical Officer for the Union Workhouse and Infirmary. Salary £40 a year.—Medical Officer for the Contagious Diseases Hospital. Salary £40 a year.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.—Resident Clinical Assistant. Board and lodging are provided free of cost, but there is no salary attached to the post.

QUEEN'S HOSPITAL, Birmingham.—Honorary Surgeon.

ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Brighton.—Assistant Physician.

ROYAL UNITED HOSPITAL, Bath.—Resident Medical Officer. Salary £100 per annum, with board and lodging.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William-street, West Strand, W.C.—House-Surgeon.

STAINES UNION.—District Medical Officer. Salary £65 per annum, exclusive of the authorised fees for surgical and midwifery cases.

TOWNSHIP OF TOXTETH-PARK, Liverpool.—Assistant Medical Officer for the Workhouse and Infirmary. Salary £100 per annum, with rations of a first-class officer and separate apartments.

VICTORIA HOSPITAL FOR CHILDREN, Queen's-road, Chelsea, S.W.—Resident Medical Officer. An honorarium of £20 for the first six months, and £30 for the second six months, will be given, and lodging in the hospital provided.

WESTMINSTER HOSPITAL, S.W.—Assistant Surgeon.

WHITEHAVEN AND WEST CUMBERLAND INFIRMARY.—House-Surgeon. Salary £120 per annum, and £30 a year for dispensing, with furnished apartments and attendance.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BARNARD, ARTHUR JOYNSON, M.R.C.S., L.R.C.P., has been appointed Senior House-Surgeon to the Royal Albert Edward Infirmary, Wigan, Lancashire, vice John Buchanan, M.D., resigned.

BIDWELL, L. A., M.R.C.S., L.S.A., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

BOND, W. A., M.A., M.D., B.C.Cantab., has been appointed Clinical Assistant in the Throat Department of St. Thomas's Hospital.

BOWEN-JONES, L.M., M.R.C.S., L.R.C.P.Lond., has been appointed Physician to the Carmarthenshire Infirmary, Carmarthen.

BROOK, W. F., M.R.C.S., L.S.A., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

BROWN, C., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

BULSTRODE, H. T., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant in the Throat Department of St. Thomas's Hospital.

CALVERT, J. T., L.R.C.P., M.R.C.S., has been reappointed Clinical Assistant in the Skin Department of St. Thomas's Hospital.

CLARKE, THOMAS, L.R.C.P.Ed., L.F.P.S.Glas., has been reappointed Medical Officer of Health for the Pewsey Rural Sanitary District.

DUNCAN, H., L.R.C.P., M.R.C.S., has been appointed Clinical Assistants in the Skin Department of St. Thomas's Hospital.

EDWARDS, WILLIAM LLOYD, M.R.C.S., L.R.C.P.Lond., has been appointed Physician to the Carmarthenshire Infirmary, Carmarthen.

ELLIS, DONALD M., M.R.C.S., L.R.C.P.Ed., has been appointed House-Surgeon to the Teignmouth Infirmary and Convalescent Home, vice A. D. Owen, M.R.C.S., L.S.A., resigned.

HALL, H. S., M.R.C.S., L.R.C.P., has been appointed Junior House-Surgeon to the Royal Albert Edward Infirmary, Wigan, Lancashire.

HARRIS, ARTHUR W., M.R.C.S., L.S.A., has been appointed Assistant Medical Officer to the Infirmary of the Holborn Union.

HAWKINS, H. P., M.R.C.S., L.S.A., has been appointed Resident House-Physician to St. Thomas's Hospital.

HESLOP, WILLIAM JOHN, L.K.Q.C.P.I., F.R.C.S.Ed., has been appointed Medical Officer of Health for the Stretford Urban Sanitary District, vice Pettinger, deceased.

HINNELL, J. S., M.R.C.S., L.S.A., has been appointed Ophthalmic Clinical Assistant to St. Thomas's Hospital.

HUTTON, J. S., M.B.Lond., L.R.C.P., M.R.C.S., has been reappointed House-Surgeon to St. Thomas's Hospital.

JONES, H. S., L.R.C.P., M.R.C.S., L.S.A., has been appointed Clinical Assistant in the Ear Department of St. Thomas's Hospital.

LESLIE, W. MURRAY, M.B., C.M.Ed., has been appointed Public Vaccinator to the Poplar Union.

MACIVOR, H. J., L.R.C.P., M.R.C.S., has been appointed Resident House-Physician to St. Thomas's Hospital.

MACKINTOSH, ANGUS, M.D., L.F.P.S.Glas., has been reappointed Medical Officer of Health for the Chesterfield Rural Sanitary District.

Digitized by Google

MCLEAN, CHARLES J. R., M.B., C.M.Ed., has been appointed Medical Officer of Health for Yeadon, near Leeds.

MASTERMAN, GEORGE FREDERICK, L.K.Q.C.P.I., M.R.C.S., has been reappointed Medical Officer of Health for the Stourport Urban Sanitary District.

NISBET, J. TAWSE, M.B., C.M.Ed., has been appointed Honorary Assistant Medical Officer to the Liverpool Infirmary for Children.

SANSOM, H. A., L.R.C.P., M.R.C.S., has been appointed Assistant House-Physician to St. Thomas's Hospital.

SMYTH, H. J., L.R.C.P., M.R.C.S., has been appointed Non-Resident House-Physician to St. Thomas's Hospital.

SOLLY, E., L.R.C.P., M.R.C.S., L.S.A., has been appointed Resident Accoucheur to St. Thomas's Hospital.

STAPLE, JAMES D., M.R.C.S., L.S.A., has been appointed Assistant House-Surgeon at the Stockport Infirmary, Stockport, vice A. J. Turner, M.D.Lond., M.R.C.S., resigned.

STAVELEY, W. H. C., L.R.C.P., M.R.C.S., has been appointed House-Surgeon to St. Thomas's Hospital.

STEVENSON, ROBERT, L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Third District of the Hunslet Union.

SUTTON, THOMAS S., M.R.C.S., L.S.A., has been appointed Medical Officer for the Second District of the Bridge Union.

WHITE, ERNEST WILLIAM, M.B.Lond., M.R.C.P.Lond., M.R.C.S., has been appointed Resident Medical Superintendent of the City Lunatic Asylum, Stone, vice Jepson, resigned.

WINFIELD-ROLL, G., M.B., B.C.Cantab., L.R.C.P., M.R.C.S., has been appointed Ophthalmic Clinical Assistant to St. Thomas's Hospital.

Births, Marriages, and Deaths.

BIRTHS

BIGGER. — On the 26th ult., at Queen's-park-gardens, Streatham-common, the wife of W. G. Bigger, M.B., M.Ch. Roy. Univ. Irel., M.R.C.S., of a daughter.

CRAWSHAW.—On the 25th ult., at 23, Trafalgar-square, Ashton-under-Lyne, the wife of S. Crawshaw, M.R.C.S.Eng., of a son.

CRITCHETT.—On the 29th ult., at 21, Harley-street, W., the wife of Anderson Critchett, of a daughter.

DAVIES.—On the 22nd ult., at Delabeche-street, Swansea, the wife of W. T. F. Davies, M.B., B.S.Lond., of a son.

GILBART-SMITH.—On the 22nd ult., at Harley-street, W., the wife of T. Gilbart-Smith, M.D., of a son (prematurely).

RAW.—On the 23th ult., at Rutland House, Oakfield-road, Anerley, S.E., the wife of William E. St. M. Raw, L.R.C.P., M.R.C.S., L.S.A., of a daughter.

RIVINGTON.—On the 31st ult., at Finsbury-square, the wife of Walter Rivington, B.A., M.B., M.S.Lond., F.R.C.S., of a son.

STEAVENSON.—On the 27th ult., at 39, Welbeck-street, Cavendish-square, the wife of W. E. Steavenson, M.D.Cantab., of a son.

TWEEDY.—On the 24th ult., at Gardiner's-row, Dublin, the wife of H. C. Tweedy, M.D., of a son.

WHITTLE.—On the 30th ult., at 65, Dyke-road, Brighton, Elizabeth, wife of Ed. Geo. Whittle, M.D.Lond., of a daughter.

MARRIAGES.

KENYON—LAW.—On the 26th ult., at St. Matthew's Church, Cheltenham, John Edward Kenyon, F.R.C.S., to Georgina Elizabeth, eldest daughter of the late Rev. Henry Law, Vicar of Chepstow, Monmouthshire.

LLOYD—HAMPSON-SIMPSON. — On the 1st inst., at Edgbaston Parish Church, by the Rev. Cresswell Strange, M.A., Vicar, Gordon Lloyd, M.S., F.R.C.S., of 22, Broad-street, Birmingham, to Marian (Minnie), eldest daughter of Mercer Hampson-Simpson, Esq., of Priory-road, Edgbaston.

STOCKER—HODGKINSON.—On the 2nd inst., at St. Luke's, Westbourne-park, by the Rev. R. J. Knowles, M.A., Vicar, George Bertram, youngest son of the late James Stocker, Esq., of Guy's Hospital, to Alice Mary, eldest daughter of the late Lieut.-Col. Cadman Hodgkinson, 28th Regiment, Bombay Native Infantry.

STURRIDGE—HAMER.—On the 2nd inst., at Wallasey Church, Cheshire, by the Rev. A. E. P. Gray, Peter Frederick Sturridge, M.R.C.S., L.R.C.P., of Kendal, to Mary Ada, second daughter of Charles Marshall Hamer, of Liscard, Cheshire.

DEATHS.

CHEESE.—On the 30th ult., at The Terrace, Hurlingham-lane, Fulham, Frederick Cheese, M.R.C.S., aged 47.

COATES. — On the 29th ult., at Dunedin, Bournemouth, Gilbert Herbert, seventh son of the late W. Martin Coates, aged 31.

COOK.—On the 28th ult., at Chepstow-place, Bayswater, John Henry Cook, M.D. (formerly of the Minories).

GAMMIE.—On the 20th ult., at Stanhope-gardens, Queen's-gate, S.W., Patrick Gammie, M.R.C.S., Surgeon-General, aged 73.

MILNE.—On the 27th ult., at Bridge of Allan, N.B., Henry Milne, M.D., late of Banff, N.B., in his 76th year.

PRITCHARD. — On the 31st ult., at Hastings, George F. Pritchard, L.K.Q.C.P.I., M.R.C.S., of Bruson House, Teynham, Kent, aged 47.

VOGAN.—On the 24th ult., at St. Mary Elms, Ipswich, after a short illness, Emma Jane, the beloved wife of James Norman Vogan, F.R.C.S., in her 22nd year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, June 6.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS. — Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE. — Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND. — 5 P.M. Meeting at the Medical Society of London, Chandos-street, Cavendish-square, W. Report of Committee and Election of Officers.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Mr. F. Henri Weiss: On the Destruction of a Permanent Tooth Pulp by an Alveolar Abscess attached to a Deciduous Molar. — Mr. Storer Bennett: (1) Dental Abnormality in a Lower Jaw from a subject who is supposed to have lived in the Stone Age; (2) Extraordinary Example of Perverted Tooth Development.—Mr. Bridgman: Case of Irregularity.—Prof. Victor Horsley: Epileptiform Neuralgia of the Fifth Nerve treated by Avulsion of the Nerve.

Tuesday, June 7.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

ROYAL INSTITUTION.—3 P.M. Rev. J. P. Mahaffy: The Hellenism of Alexander's Empire—Macedonia and Greece.

Wednesday, June 8.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET. — Operations, 9 A.M.; Saturday, same hour.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Christopher Heath: Certain Diseases of the Jaws—Cystic Diseases of the Jaws.

ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. G. Massee: Monograph of the Genus Lycoperdon. — Profs. T. Rupert Jones and C. D. Sherborn: Remarks on the Foraminifera, with especial reference to their Variability of Form, illustrated by the Cristellarians.

EPIDEMIOLOGICAL SOCIETY OF LONDON. — 8 P.M. Annual General Meeting. Dr. George Turner: Diphtheria.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown by Drs. R. T. Smith, Edis, Granville Bantock, and others.—Mr. Lawson Tait: The Principles of Flap-splitting in Plastic Surgery.

Thursday, June 9.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Rev. J. P. Mahaffy: The Hellenism of Alexander's Empire—Egypt.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM. — 8.30 P.M. Living and Card Specimens at 8 P.M.:—Mr. W. J. Collins: Extensive Hæmorrhage into Blind Eye with Coarctation of Retina.—Mr. Higgens: Unusual Form of Coloboma of Iris.—Mr. G. B. Walker: (1) Sequel to case of Exophthalmos; (2) Sequel to case of Cyclotomy in Glaucoma.—Mr. Story: Experimental Demonstration on the Pathology of Glaucoma.—Mr. Silcock: Sequel to case of Central Choroidal Hæmorrhage. Papers:—Mr. Story: Case of Complete Blindness of Right Eye with Temporal Hemianopsia of Left Eye.—Mr. Hill Griffith: On the Permeability of the Suspensory Ligament by Organised Substances.—Mr. Brailey: Recurrent Choroido-Retinitis in region of Macula Lutea.—Mr. Nettleship: Two cases of Quinine Amblyopia.

Friday, June 10.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Christopher Heath: Certain Diseases of the Jaws—Tumours of the Jaws.

ROYAL INSTITUTION.—9 P.M. Mr. Thomas Hodgkin: Aquileia the Precursor of Venice.

Saturday, June 11.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Rev. J. P. Mahaffy: The Hellenism of Alexander's Empire—Syria.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

MEDICAL STUDENTS AND THE JUBILEE.

ON the occasion of the recent celebration of the birthday of the Emperor of Germany the students of Berlin turned out in force to show their loyalty to their sovereign. In a few days we shall be celebrating the completion of our Queen's fifty years' reign; but as yet we have not heard that the medical students of London, a large and important part of the community, are making any attempt to take formal part in the celebration. Our attention has been called to this omission by two correspondents, who suggest that a congratulatory address be drawn up and signed; that the students of all the hospitals should turn out in evening dress, with white flowers in their button-holes, and should march in procession to Her Majesty, drawing up outside the palace; and that a deputation consisting of one representative from each hospital should present the address, the whole force, on the return of the deputation, giving three cheers for their Queen. If anything of this sort is to be done, there is no time to be lost. What is done must be done promptly. The idea is worthy of consideration.

Justice.—A medical man under promise not to practise as a surgeon and apothecary within ten miles of a given centre is clearly also prevented from practising as a *physician*, a term which does not now bear the restricted meaning which it had fifty years ago, but embraces a great part of the cases of ordinary practice.

Beta.—The qualifications mentioned are sufficient for the recovery of midwifery fees, either singly or combined.

Junior.—Nothing is definitely known on the points mentioned.

THE INCOME TAX.

To the Editors of THE LANCET.

SIRS,—I wish to get information on the following point, and perhaps some of your readers may be able to help me. I took over a practice in the autumn of last year, but did not take the book debts with it. Notwithstanding this, the surveyor of taxes required me to pay half my predecessor's income tax; but I refused to do so. He then called upon me to give a statement of my book debts, though my bills cannot be sent out till midsummer, and on this return, when he gets it, he proposes to base his assessment. I should say my actual receipts for six months ending March 31st are less by £10 than the working expenses. Can I be required to pay on debts that have not yet been claimed, but on which when paid I shall have to pay income tax for the year following? What is the best course to take?—I am, Sirs, yours obediently,

May, 1887. A COUNTRY PRACTITIONER.

THE CASE OF MR. CHARLES GAFFNEY.

DR. GLOVER begs to acknowledge the receipt of the following sums towards helping the Misses Gaffney in maintaining their brother:—J. G. G., £2 2s.; J. A., £1 1s.; H. S. H., £1 1s.; Omega, 10s.

Mr. G. Schofield (Bournemouth).—The appointment is not a public one.

TREATMENT OF TÆNIA SOLIUM.

To the Editors of THE LANCET.

SIRS,—In answer to "Puzzled," I beg to forward the following observations:—

During my stay in South Africa I treated many cases, myself included, and always with success. The great point in the treatment of tapeworm is to expose the head, which is attached to the intestine by its hooklets. So long as the head be covered with fæces no medicine will do much good. My treatment is as follows:—The day before giving the worm medicine I allow no food of any kind except plain beef tea, or other very thin soup, and very little even of these. The first morning I give one drachm of compound jalap powder, which generally operates three or four times during the day, and effectually clears out the bowels, bringing away at the same time large portions of the worm. The patient, of course, keeps quiet in the house. On the second morning, on an empty stomach, I give a draught consisting of from two to three drachms of oil of turpentine and one drachm of oil of male fern in sweetened emulsion. After an hour or so I give a dose of castor oil. It will not be long before the whole of the worm with its head will have passed, which will be found on proper examination of the stools. The patient can then take his usual diet, and the following day will be well. I have never known this treatment to fail. The above doses, of course, are intended for adults. The frequent failure of the oil of male fern as an anthelmintic is, I believe, attributable to the smallness of the dose exhibited, less than a drachm for an adult being useless. I may here state that I believe every native in South Africa to be infected with one or two tapeworms. I am, Sirs, yours faithfully,

Cheltenham, May, 1887. FRED. A. A. SMYTH, M.D.

To the Editors of THE LANCET.

SIRS,—In reply to "Puzzled" I write to say that it is useless to rely upon any of the reputed remedies for tapeworm, unless the patient is in the first place well purged, and afterwards properly dieted. The plan I have adopted, and which I have never found to fail, is, supposing the patient to be an adult male, to give an ounce of castor oil; this clears the intestines, so that the worm has nothing to hold on to. For the next twenty-four hours feed the patient on beef-tea, gruel, raw eggs, allowing neither milk nor anything solid. Then give one drachm of oil of male fern emulsified with yelk of egg and a little syrup and gum, eight hours after which give another dose of castor oil. This removes the parasite without distressing the patient. Should the dose of male fern be vomited, before repeating it apply a mustard and linseed meal poultice to the epigastrium. By the above treatment I recently ejected a tenant of nine years' residence.—I am, Sirs, yours obediently,

May 30th, 1887. E. W., L.S.A. &c.,

To the Editors of THE LANCET.

SIRS,—In reply to the letter in your issue of May 28th regarding the non-success of the various remedies for tænia solium prescribed by "Puzzled," permit me to recommend my prescription and after-treatment for the entire expulsion of tænia with its head. The patient, an adult, is to take the following draught on awakening about 4 o'clock in the morning:—Six drachms of castor oil, one drachm of oil of male fern, fifteen minims of liq. potassæ, and ten minims of spirit of peppermint. For breakfast a small plate of Scotch porridge and a cup of hot tea. By following this treatment twice a week he will succeed after the third or fourth draught in expelling the worm with its head.

I am, Sirs, yours obediently,

Manchester, June 1st, 1887. H. R. H. PEARE, L.K.Q.C.P.I., &c.

To the Editors of THE LANCET.

SIRS,—Your correspondent, "Puzzled," should starve his patient for so many hours, say seven. Kill the worm at bedtime with a full dose of fresh male fern—a drachm. Empty the bowels next morning with a large dose of castor oil. Allow the patient to drink tea without milk and sugar till the bowels have well acted. Afterwards, in four hours, sanction a plate of mashed potatoes. Repeat this twice during three days. After a short interval of a few days repeat again, and if necessary again. This plan I have on several occasions found to be a certain remedy; but it must be carried out most rigidly. It is what all practical physicians would recommend. I am, Sirs, yours faithfully,

Baschurch, May 29th, 1887. J. F. BRISCOE.

To the Editors of THE LANCET.

SIRS,—In Dr. Lionel S. Beale's work "The Microscope in Medicine" there is a section headed "Means of Procuring the Head of the Tapeworm." I followed these directions closely, while I bore in mind the caution given by Dr. T. Spencer Cobbold in his book on "Worms," where he says: "The important thing is to be sure that your pharmaceutical preparations are the very best that can be made. Inferior drugs will cause you much disappointment." I had my oil of male fern freshly made by one of our best chemists, and administered in this case two drachms, with the desired result. I am, Sirs, yours very truly,

Brighton, May 28th, 1887. F. J. SPRANGER.

HOUSE SANITATION.

Mr. R. Fitzroy Benham calls attention to the existing method of construction of houses which allow smells to pass from the basin of the watercloset when it is used, beneath the seat, and travel along the joists into other parts of the house, and he suggests the rim of the basin being provided with an indiarubber lining which would effectually block up the space intervening between the seat and the rim.

Dr. J. B. Macnaughton.—The coroner certainly acted within his legal rights in ordering another medical man to make the post-mortem examination. We are inclined to think that whenever the death seems not improbably due to violence, it is well that the responsibility should be shared by two medical men, especially as the gentleman in charge of the case during life might be charged by unscrupulous or careless persons with having acted in other than the best interests of the patient. We advise our correspondent to view this case in a philosophical spirit.

One of them.—As the Medical Register was published on April 29th, clearly not "one of them"—new members of the College of Surgeons—in the list of May 7th could appear.

NEW SOUTH WALES.

To the Editors of THE LANCET.

SIRS,—In reply to the questions asked by "Viator" in your issue of May 28th, I beg to state that there are no peculiar endemic or epidemic diseases in New South Wales. Nearly all the diseases prevalent in Great Britain are met with in practice, but the general mortality is low. Typhus fever and small-pox are unknown, except when accidentally introduced by immigrants. Sydney had a short epidemic of small-pox lately produced in this way. Typhoid fever is rather prevalent, and there have been various severe epidemics of scarlatina and measles. Diphtheria is relatively common. Respiratory disease is decidedly less frequent than in Great Britain, whereas diseases of the nervous and digestive systems exceed the home average. Parasitic disease, especially hydatids, is common. Snake-bite is, perhaps, the only unfamiliar affection which the practitioner is called upon to treat. The mortality from it is low compared with the number of accidents reported. The chief towns are well supplied with all the requisites of practice, but the prices charged are high. Your correspondent would do well to go out thoroughly equipped with the usual *armamentarium*, but no special selection of drugs or instruments need be made. The conditions of practice vary much according as the practitioner settles in one of the large towns or in a rural district. In the former case medical life and practice do not differ materially from the experience of the home country. In the latter case the practitioner must carry with him such accessories of civilisation as may be necessary for comfort and medical practice.

I am, Sirs, yours faithfully,

Belfast, May, 1887. JAMES ALEX. LINDSAY, M.A., M.D.

In reference to one part of "Viator's" query, Messrs. Mayer and Meltzer of Great Portland-street write that they have a branch establishment in Melbourne, where surgical instruments of all kinds may be obtained.

PLACENTA PRÆVIA.

To the Editors of THE LANCET.

SIRS,—Mr. Logan's case in THE LANCET of May 20th has induced me to send you the following, should you deem it of sufficient interest for insertion.

On April 28th last I was called to a primipara aged about twenty-six. On arrival I found the patient in bed, looking and feeling remarkably well. I was told that the contents of the uterus had been expelled. On examination I found the vagina perfectly free from blood clot; in fact, my digit was not even stained with blood. The vaginal canal was somewhat tightly contracted. In the chamber vessel there was a fœtus between four and five months old, with the placenta attached to the vertex. The head was exceptionally large. There was a very slight sanious discharge for two or three days after this. I may mention that the menstrual discharge had been always very scanty and that three weeks previously to the miscarriage the patient fell into a small brook; the accident, however, gave rise to no unpleasant symptoms more than the shock at the time. As the peculiarity of the attachment of the placenta and the entire absence of hæmorrhage at birth were unique in my experience, I thought the case might be of interest to the profession.—I am, Sir, yours faithfully,

Wadebridge, May 28th, 1887. F. G. STEWART, M.R.C.S., L.S.A.

THREADWORM.

To the Editors of THE LANCET.

SIRS,—In the case of your correspondent, "M.R.C.S.," perhaps the vagina is a nidus for this worm, the oxyuris vermicularis, presuming the patient to be a female. If so, the vagina should be washed with a carbolic lotion, any ulceration of the os uteri treated with $AgNO_3$, the perineum anointed with a carbolic or mercurial ointment, as a poison to these migratory creatures, and a rectal injection of iron, salt, quassia, or oakbark employed, coupled with the administration of iron and bark internally and an occasional purge. The diet to be regulated. Such vegetables as greens are to be avoided.

I am, Sirs, yours faithfully,

Baschurch, May 29th, 1887. J. F. BRESCOE.

THE CHINA MEDICAL MISSIONARY JOURNAL.

THE Medical Missionary Association of China has commenced to issue a quarterly journal, which, if we may judge by the first number, will contain a good deal of valuable scientific matter, connected especially, of course, with the Oriental aspects of disease, in addition to articles of missionary interest. The columns of the journal are, we are glad to note, by no means confined to missionaries, but are equally open to all qualified practitioners in China. A space is also reserved for articles in the Chinese language. From a list given there appear to be at present seventy-nine medical missionaries in China, Corea, and Siam, belonging to twenty different societies. The majority are Americans, but thirty-three are British subjects. Fifteen ladies, thirteen of whom are Americans, are included in the list. The Rev. L. H. Gulick, M.D., of Shanghai, may be addressed for further information concerning the association.

Pour y Parvenir, and D.—Application should be made to the Directors or Commissioners of Prisons, and the appointments are in the hands of the chairman, Sir E. Du Cane.

Mr. T. L. Horner.—Heath's Operative Surgery; Stephen Smith's Principles and Practice of Operative Surgery.

THE COMMEMORATION OF THE QUEEN'S JUBILEE BY THE MEDICAL PROFESSION.

To the Editors of THE LANCET.

SIRS,—I have been waiting to see if any of the leading members of our profession would begin some movement to commemorate the jubilee of Her Most Gracious Majesty the Queen, and that would also at the same time have the effect of benefiting the less fortunate members of the profession to which we belong, but up to the present time I have seen no sign of anything being done in that direction. I know that it is from no want of loyalty that the members of the medical profession have so far not taken combined action to mark their high regard for the jubilee of our beloved Queen in some practical and solid way, but I believe it is because they are waiting for someone to initiate a movement that would recommend itself to their approval for that purpose. There is scarcely a week passes but that an appeal is made to the profession for assistance on behalf of some "object of charity" belonging to our body by reason of old age, sickness, misfortune, or death, and knowing this, and seeing that the various sections of the community are vieing with each other to celebrate the Queen's Jubilee in some substantial form, I venture to ask you to lend your aid and influence to bring about such a movement that will be creditable to our profession and a great gain to those who have particular claims upon our sympathies, and who look to us to smooth some of the rough places of this life, and aid them in procuring the creature comforts to make life bearable. When we take into account the number of members (16,000) belonging to the medical profession in this country, and know the great want there is of help for the sick and needy amongst them and their families, I cannot but think that it only requires your help in pointing out the duty of our members to do something worthy of our noble profession to alleviate the wants of our less fortunate brethren in order to secure its accomplishment. We see what can be done by united action in raising money by such examples as those of the committees of the "Women's Jubilee Offering to the Queen"; and I think we have sufficient men of influence amongst us who might be prevailed upon to act as a central committee, and to call meetings of our professional brethren in every town throughout the kingdom in order to raise subscriptions for the purpose I have indicated; and I believe if that were done the results would be most satisfactory. When we see the number of almshouses that are empty at Epsom solely through the want of funds, and that the number of applicants for pensions, &c., is so much in excess of the funds that are at the disposal of the Medical Benevolent Society in connexion with the college at Epsom, I think it is quite time we were up and doing. If the matter is thoroughly taken in hand, I feel sure that before many months are past we should be in a position to go to the head-master of the college at Epsom and ask his advice as to how to expend a sum of £10,000.

I now, Sirs, leave the matter in your hands, and ask your powerful aid in furthering this much-needed object; and there can be no doubt that the success of such a movement would not only be a wise and beneficent act to testify our loyalty and appreciation of the blessings conferred upon our country during the reign of our gracious Sovereign, but would also be an honour to our profession and a means of rendering assistance and conferring comfort and happiness on many. I shall be glad to give ten guineas towards any fund that may be begun in connexion with the Medical College at Epsom.

I am, Sirs, yours faithfully,

Mirion House, Crewe, May 18th, 1887. JAMES ATKINSON.

"CHRONIC RHEUMATIC ARTHRITIS."

To the Editors of THE LANCET.

SIRS,—I would recommend your correspondent who signs himself "Medicus" in THE LANCET of to-day to try the following treatment in the case he mentions:—Five-drop doses of tincture of iodine three times a day, and coca wine at night to promote sleep. I have found coca wine very useful in cases where opium is contra-indicated.

I am, Sirs, yours truly,

Bridgend, May 28th, 1887. W. EDMUND THOMAS, L.R.C.P., &c.

Digitized by Google

WANT OF A CHINESE MEDICAL DICTIONARY.

A WANT has long been felt of a dictionary of medical terms for all China, the words employed in one part of the empire often conveying no meaning to those living in another part. Thus a Chinaman from the north is said to have hunted all over Canton and Hong Kong for iodide of potassium without being able to make anyone understand what he wanted.

Mr. A. E. Barker.—A proof of the paper will be forwarded in the course of a few days.

Dr. Mc Clure (Cromer).—The paper has been received and will be published shortly. The other case mentioned may be forwarded.

CONVERTIBLE CARRIAGE.

To the Editors of THE LANCET.

SIRS,—I have lately had a carriage built which presents some peculiarities which may be interesting to your readers. By various alterations it can be turned into a brougham, single seated; a victoria, with hood; or a park phaeton, each complete in itself. The alteration from victoria to park phaeton can be accomplished in about two minutes, and that from victoria to brougham in a little longer space of time. The advantages gained are, of course,—(1) that for the price of one carriage I have three; (2) that no more room in stable is required than for one carriage; (3) that I can vary my vehicle according to the weather, and either drive myself in the park phaeton or be driven in the victoria or brougham; and (4) only one tax for three carriages. There is nothing in the victoria or park phaeton that looks different from the ordinary carriages of this type. In the brougham the only discernible difference is that the wings are retained. I shall be happy to show any of your readers the metamorphosis, which I can strongly recommend for medical men, especially for those whose income is not in proportion to their desires. I am, Sirs, yours faithfully,

A. GEORGE BATEMAN, M.B.

Longridge-road, S. Kensington, May 30th, 1887.

A Guy's Man cannot be blamed for not going to a case against the wish of the parents.

H. B.—It is better to follow the custom heretofore observed in the place.

"A NEW UVULATOME."

To the Editors of THE LANCET.

SIRS,—I have only just been able to procure a copy of Mathim's Catalogue, in which Dr. Warren says is depicted a uvulatome invented by him in 1855, and precisely similar to that claimed as my invention in THE LANCET of May 7th. His instrument appears to be constructed on the principle of flower-scissors, with a slight curve *downwards*, thereby exposing a wide cut surface anteriorly. This is exactly what my instrument would avoid.

I am, Sirs, yours faithfully,

GREVILLE MACDONALD, M.D. Lond.

Upper Wimpole-street, W., May, 1887.

Mr. E. B. Williams will see by a general notice which appears weekly in our columns that we do not undertake to return MSS. not used.

"SWEATING OF THE FEET."

To the Editors of THE LANCET.

SIRS,—"A Sufferer" asks, in your last issue, for a remedy for the above. Presuming that there is no obvious cause for the sweating, and that it is confined to the feet, your correspondent will derive considerable benefit, if not absolute cure, from the use of digitated wool socks and felt cloth shoes. I am, Sirs, yours faithfully,

May 30th, 1887. BERNARD O'CONNOR.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Hulke, London; Sir W. Mac Cormac, London; Dr. L. Marshall, Nottingham; Dr. J. W. Ogle, London; Sir G. Young, London; Mr. E. The Cavendish Lecture

ON A

SPEEDY AND SOMETIMES SUCCESSFUL METHOD OF TREATING HAY FEVER.

Delivered before the West London Medico-Chirurgical Society,

BY SIR ANDREW CLARK, BART., M.D., F.R.S.,
EMERITUS PROFESSOR OF CLINICAL MEDICINE TO THE LONDON HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—It has been sometimes said by way of reproach that the scientific workers in medicine, although eager in the pursuit of knowledge for its own sake, were careless of its practical applications to the treatment of disease. If at any time this reproach was a just one I do not know, but beyond all manner of doubt it would not be a just one now, for in almost all countries, and in nearly every school in every country, you can see, not only the earnest pursuit of knowledge, but the most zealous efforts to force it into fruit for the uses of men, and in the study of no subject could you find a better proof of this than in the study of hay fever, of which I am about to speak. From Blackley of Manchester to Mackenzie of Baltimore you will find a succession of inquirers whose efforts to discover the nature of this malady have been accompanied by efforts equally earnest and persevering to discover its most appropriate treatment; and from America, the most earnest and persevering of all countries at work, we have received the largest and best fruits of this double pursuit. To-night the plan of treatment of hay fever which I shall have the privilege of submitting to your consideration is entirely founded upon a physiological study of the disease. It is, however, with the results of this study only in so far as they bear broadly and directly upon treatment that I propose to occupy myself. With minute discussions as to the nature of hay fever, its physiological and pathological relations, and the causal agencies engaged in its evolution, I shall have to-night only an indirect concern. Nevertheless, as I wish to set forth the true grounds for a rational treatment of this malady, such discussions cannot be passed over entirely.

Before proceeding further I wish to pause for a moment and advert to the name by which this malady is known. From nothing has medicine suffered more than from hypothetical naming. What may seem to be the correct and adequate hypothesis of to-day may become the incorrect and inadequate hypothesis of to-morrow; and when the true nature of a malady is discovered, the diffusion of the discovery is hindered, if not prevented, by the retention of a name which, established by custom and continued from convenience, conceals the truth and perpetuates error. I could advance few better illustrations of this than the naming of the disease under consideration. The epithets of "hay fever," "hay asthma," "pollen fever," "rose cold," and "peach cold" are widely open to this objection. They withdraw the attention from internal states, and they tend to narrow our ideas of causality within the limits of outward things. It is true that the pollen of certain grasses is the most common exciting agent of the paroxysm of hay fever, but it is also true—for it has been demonstrably proved—that the paroxysm can be excited not only by other external agents, such as light and heat and dust, but also by local affections of the nose and throat, by irritations propagated from distant parts, and by influences degenerated *de novo* in some part of the central nervous system. It is only of late, and through researches made for the most part in America, that we have come to a knowledge of these facts. Even there, however, the tendency to hypothetical naming continues, and the term proposed by Mackenzie of Baltimore, to whom we owe so much of what is best in our recent knowledge of this subject, is not free from grave objections. He calls the disease "periodic vaso-motor coryza," but in this designation there is involved an hypothesis which to-day may be doubted and to-morrow disproved. Nor are the epithets proposed by myself—"periodic specific coryza" and "periodic nervous coryza"—free from just and grave objections. We are thus in need of a proper name for our malady. No one can be rightly framed except out of its commoner physical characteristics, and no one can be safely used unless it shall imply no hypothesis and be capable of remaining always the same, however much our theories of the disease may change.

Of the innumerable persons exposed, in similar if not identical conditions, to the exciting causes of hay fever, only a few are affected with the disease, and of those few there are, strange to say, scarcely any among agricultural labourers and gardeners, who are habitually exposed to the pollen of grasses believed by some authors to be the sole causal agents of the development of the asthmatic paroxysm. It seems therefore only fair to conclude that in the evolution of the malady some other agent than the external exciting cause must be directly concerned. Further investigation proves this conclusion to be correct. From experimental examination we learn the existence of a second factor which resides in the mucous membrane of the nose, mouth, pharynx, and eyes, which mainly concerns the nerves of these parts, and which manifests itself in all their histological constituents by a peculiar irritability of reaction to certain excitants. Furthermore when, in cases exhibiting this peculiar local irritability, we pursue our inquiries into the characters of the constitutional state associated with it, we discover certain *bizarre* symptoms of disorder which belong exclusively to the nervous types of organisation, and which stamp the organism exhibiting them as specifically and pathologically nervous. Lastly, if, pursuing our investigations still further, we institute an analysis of the differentiæ distinguishing the nervous constitution in this disease from the nervous constitution of cognate affections, we are led to the conclusion that they reside for the most part in the respiratory and vaso-motor centres and in the ganglia connecting and connected with both. In this way we discover reasons for believing that there are three great factors concerned in the evolution of hay fever: the nervous constitution, the irritable local state, and the exciting cause. As a general rule, to which there are some remarkable exceptions, all these factors, although in varying degrees, co-operate in the development of an attack of hay fever. Concerning each of them I have to offer a few observations which will make plain the ground upon which a rational treatment of this malady can be based.

The nervous constitution associated with hay fever is sometimes inherited and sometimes acquired. For the most part inheritance comes from the arthritic and the nervous. When acquired, it is acquired most easily by those who lead laborious sedentary and intellectual lives, as well as by those who, avoiding the difficulties and discipline of life, seek luxury with ease, by those who prefer excitement to duty, and by those who become weak through failure to exercise their strength. And when once hay fever appears, it exhibits still further the closeness of its relationships to the nervous system by choosing the man before the woman, the educated before the ignorant, the gentle before the rude, the courtier before the clown. Some of the more general affinities of hay fever are harder to be understood. It prefers the temperate to the torrid zone; it seeks the city before the country, and out of every climate which it visits it chooses for its subjects the Anglo-Saxon, or at least English-speaking race.

And now, concerning the second factor in the evolution of hay fever, the condition of the mucous membrane of the nasal cavities and parts adjacent, we have divers and some diverse views. All observers are agreed that there is some pathological condition of the affected parts, but no two of them are agreed as to its exact nature. For my own part, I conclude from the investigations which I have pursued into the matter that there is one fundamental condition which reconciles all these varied and sometimes opposing views. This condition is one of irritability, and the irritability is of a sort which involves the nervous vascular lymphatic and cellular constituents of the affected parts, and when excited disturbs the chemical morphological and secretory changes taking place therein. When this local irritability is provoked into action there arise a series of local structural changes which are all but characteristic of the paroxysm of hay

Digitized by Google

fever. The erectile tissue becomes distended, the bloodvessels are gorged with blood, groups of lymph cells fill the lymphatic spaces, the mucosa is crowded with migrating leucocytes, younger epithelial cells are vacuolating and proliferating, secretion is increased in quantity and altered in character and composition, sensation is sharpened, altered, or benumbed, and the whole metabolism of the affected region is profoundly disordered. These local changes are always present in the paroxysm of hay fever, and whenever they concur and co-operate it may be safely said that hay fever is present. When this local irritability exists in an extreme degree, almost any exciting agent—an odour or vapour, dust, a touch, light, or heat—will quickly call forth the whole series of structural changes already described as almost exclusively characteristic of the paroxysm of hay fever.

And now let me speak shortly of the third factor engaged in the evolution of this malady—that is, of the external exciting or determining causes to which it is commonly ascribed. Authors in general, from Gordon in 1829 to Mackenzie in 1885, advocated the view that the paroxysm of hay fever is due in persons of a certain idiosyncrasy exclusively to the action of the pollen of grasses or of flowers upon the mucous membrane of the nasal cavities and adjacent parts. In support of this view, it is contended that the disease occurs only during the season when certain grasses and flowers are in blossom, that it may be artificially induced by the application of pollen to the nasal mucous membrane, and that it may be prevented from occurring, or may be cured when present, by dwelling on board ship at sea, where no pollen is to be found. Now, whilst it must be admitted that these contentions are in some degree just, and that the most common exciting cause of the hay fever lies in the action of the pollen of certain plants upon the nasal mucous membrane, it cannot be denied that they require qualification, and that they are inadequate to a complete explanation of all the facts which make up the history of this disease. For on this side it may be contended as proved that the malady is less common among agricultural labourers and gardeners than among other persons, that sometimes it occurs at other seasons of the year than in the hay season, that it has been induced by local irritants in which pollen did not exist, that it has occasionally arisen in consequence of irritation in a part with which the nose is in sympathy, and that the mere action by itself of pollen upon the nasal mucous membrane is insufficient to provoke a complete paroxysm of hay fever.

For myself, I am compelled by my inquiries to adopt the view that in the evolution of almost every attack of this malady the three factors already mentioned are at work—the nervous constitution, the local irritability, the external exciting cause; and that whilst this last is most commonly a pollen acting more in virtue of its physical characters than of its intimate nature, it may be any other agent capable of calling into action the irritability of the parts concerned in the mucous membrane of the nose. And now, when we consider these facts and theories of hay fever with the view of framing a rational plan of treatment, we find ourselves beset on every side with difficulties. Theoretically, the objects to be achieved by treatment are the soothing and strengthening of the general nervous system, the allaying of local irritability, and the removal of the exciting cause. To remove the exciting cause, or rather, speaking correctly, to remove the susceptible person from it, is to prevent the on-coming of the disease; and if you send him to sea, or to the summit of some Alpine height, you will assuredly succeed. There are, however, many who cannot follow this counsel, and who must remain under the influence of the exciting cause of the malady. What can be done for the patient in such circumstances? We may strive to strengthen by tonics the weak and irritable nervous constitution; and Morell Mackenzie has had some success with valerianate of zinc and assafœtida, whilst Blackley has failed with every drug which he has tried. By common confession, general treatment, although not useful, is never by itself successful.

We are therefore compelled to turn to the study of local treatment as the chief mode of relieving or curing the disease. There are three plans of local treatment. The first plan is to allay the irritability of the nasal mucous membranes. The second plan is to exhaust the irritability of the nasal mucous membrane. The third plan is to remove or to modify, or to destroy by caustic, or by cautery, galvanic or igneous, such portions of the nasal mucous membrane as are found, or believed to be, the seat of the pathogenic irritability. This third and most radical plan of treatment is practised for the most part in America, and in the hands of Daly of Pittsburg, Roe of Rochester, and Mackenzie of Baltimore, it has been followed by lasting and signal success. But as there are not as yet at our disposal materials sufficient to form a critical estimate of the relative value of this form of treatment, as I have myself no personal experience of the practice of it, and as in this imperfect lecture my chief object is to submit to your consideration the plan of treatment designed and practised by myself, I dismiss for the present from further consideration all operative procedures of this radical kind.

The first plan of treatment proposes to prevent or to cure hay fever by allaying the pathogenic irritability of the mucous membrane. This was the object which I endeavoured to achieve when I began my therapeutical experiments in the treatment of this disease. From trials extending over several years no remedies of this sort except aconitina and atropina returned me any results of the smallest value, and the result returned by the use of these alkaloids was so insignificant, and the effects of following it were sometimes so disagreeable, that I abandoned my inquiries in this direction. The introduction of cocaine, however, and its recent employment in the treatment of hay fever, induced me to re-open my experiments in this direction. At first my success was considerable, for three out of five cases were immediately relieved, and the relief was maintained by the frequent renewal of the application of cocaine to the nasal mucous membrane. But when last year my experience of the use of this drug somewhat increased, my success in using it diminished. In one case the application failed and disagreed. In another case it neither disagreed nor failed, but I was quite unable to discover in the patients the grounds of this difference of action. Nevertheless, although it appears to me that the success of cocaine as a local remedy in hay fever has been overrated, although the necessity of frequent application is troublesome, and although its use is not free from inconveniences which might eventually prove something worse, I am of opinion that its success and its comparative freedom from injurious consequences are sufficient to justify with careful watching a longer and larger trial. There are three ways of using cocaine in the local treatment of hay fever: it may be used in the form of a solution, of a spray, or of a nasal bougie. Personally, I prefer to use a solution varying in strength from 5 to 15 per cent., and I apply it to the interior of the nose and the back of the soft palate by means of a large camel-hair pencil attached to an aluminium shank and bent at an appropriate angle. For use in the form of nasal bougies, from a quarter of a grain or more of the hydrochlorate of cocaine is dissolved in a mixture of gelatine and glycerine, and made of different weights and shapes according to the peculiarities of the case on which they are to be employed. For using cocaine in the form of spray, some efficient and ingenious spray producers have been invented. Many of them are furnished with nozzles, so constructed that the spray can be applied directly to almost any part of the nasal and pharyngeal cavities. These spray producers, with weak cocaine solutions, are sometimes very useful in allaying the small but still troublesome irritation which, in the intervals of the hay fever paroxysms, are apt to arise in the eyes and mouth. By the great kindness of Mr. Martindale, to whose pains, intelligence, and accuracy in matters of this kind we are all so much indebted, I am enabled to show all these preparations of cocaine and all the instruments wherewith they are used.

I come now to consider the second plan proposed for the local treatment of hay fever. The object of this plan, which does not exclude constitutional treatment, is to subdue the irritability of the nasal mucous membrane to such an extent that it shall no longer react to special or common irritants, whether pollen or dust, in a pathogenic manner. In the first place the patient is put upon such a regimen as will conduce most to the improvement of his general health. He is instructed to have a simple but liberal dietary, to be extremely moderate in the use of alcoholic stimulants, to have daily exercise, to follow early hours, and to continue, if that be possible, even at the cost of suffering his ordinary occupations. If the patient is very weak, he is instructed to take with meals drachm doses of Easton's syrup with three or more drops of the solution of arsenic hydrochloric. If he is nervous as well as weak I prescribe for him in their full respective doses tartarized iron, ammonium bromide,

Digitized by Google

tincture of nux vomica, and a solution of arseniate of soda. In some cases I think that I have seen great benefit follow the use, thrice a day, of five grains of sulphate of quinine, dissolved in citric acid and given in effervescence with carbonate of ammonia.

For the strictly local treatment there are required a common laryngeal brush and a carbolic mixture. This mixture is composed of glycerine of carbolic acid one ounce, hydrochlorate of quinine one drachm, and a thousandth part of perchloride of mercury. Heat will be required in order to dissolve the whole of the quinine, for without heat Mr. Martindale informs me that the glycerine of carbolic acid will dissolve only half the quantity prescribed.

Let me now describe the method of procedure to be followed in applying the carbolic acid mixture to the mucous membrane of the nasal cavities. If there is much mucus in the nostrils, cleanse them by means of a douche of warm water containing boroglyceride,[1] in the proportion of an ounce to the pint. Dip the laryngeal brush in the carbolic acid mixture, and see that the brush is full but not overflowing. Place the left hand on the left side of the forehead, and the thumb on the tip of the nose, with the shank of the brush between the thumb and two forefingers of the right hand, and the brush itself directed upwards, push it gently but firmly into one of the nostrils, carry it as high as you can without inflicting injury, move it about so as to bring the mixture in contact with as much as possible of the interior of the upper part of the nostril, and then withdraw it. With another brush filled with the carbolic acid mixture, or with the same brush washed, dried, and replenished, you complete in the manner following the two operations required for each nostril. Having the left hand in the position already described, and the right hand holding the laryngeal brush, with the hair pencil directed forward from the body of the operator, push the brush along the floor of the nostril into the pharynx, and after insuring free contact with the adjacent parts, withdraw it. If during the operation the brush is over-full, some of the carbolic mixture will fall into the throat and excite coughing or some other discomfort. When you have thus finished the treatment of one nostril, and carefully removed any of the carbolic acid mixture which may have been spilt upon the nose or lips, you will proceed to treat the second nostril in exactly the same manner as you have dealt with the first. During the performance of these manœuvres great assistance will be obtained from the left hand of the operator being placed over the left side of the forehead and face of the patient. With this hand the operator can adjust the patient's head to the various movements of the laryngeal brush, and with the same hand placed on the tip of the patient's nose the opening of the patient's nostril can be adjusted to a convenient size and shape. When the local effects of a paroxysm are severe, and have extended to the back part of the soft palate, it will be desirable to introduce through the mouth into the pharynx the laryngeal brush moderately filled with the carbolic acid mixture, and there, by a manœuvre easily acquired and practised, to brush the posterior surface of the soft palate and the adjacent parts. The immediate effects of these manœuvres differ in different persons, and in the same person at different times. In all cases the effects are more or less disagreeable, and last from half an hour to half a day. Sometimes a little blood-stained mucus is discharged from the nose and throat; sometimes there is a slight frontal headache; sometimes there is a trivial cough, and occasionally you will have developed all the local phenomena of a paroxysm of hay fever.

When advising a patient with hay fever to submit to this plan of treatment for its relief, I have found it expedient to warn him beforehand of the disagreeable effects which sometimes follow the application of the carbolic mixture, and to assure him that they are both brief in duration and devoid of danger. When this warning is withheld, some patients will grossly exaggerate their sufferings, ascribe all sorts of injurious consequences to the application, and cover the physician with undeserved reproaches. Sometimes a single application of the carbolic acid mixture is sufficient to prevent for a whole season the return of the hay fever paroxysm, and four times within my own knowledge it has never reappeared. Usually two or three applications are necessary to ensure a full chance of success. The length of the interval between the applications must be determined by the character of the immediate effects. If these are mild, the application may be renewed on alternate days; but if severe, at least three days should elapse between succeeding applications.

Of the measure of success which has followed this treatment of hay fever, now practised over twenty years, I am unable to speak with exactitude. Patients when relieved seldom, and when unrelieved never, return to record their experience, and I have been unable to get at the subsequent histories of more than a third of the number of persons whom I have treated. It is, however, my conviction that of this roughly estimated third whose cases I have been able to follow, a half has been cured for the season, and four persons have been cured "for good." This, you will say justly, is not a success of which to boast. Quite so. But if you will compare the results of this treatment with the results of every other treatment, not excepting the cocaine treatment, which is its closest rival, you will have to confess that, however small the measure of success, it is not one which you can afford to despise. At any rate, a communication of this kind is entitled to your indulgence, inasmuch as it is an honest, although a very humble, endeavour to press pathology into practice, and to take away the reproach which has been cast upon us of ignoring or of repudiating the natural and just alliance which should unite in closest relationships the science with the art of medicine.

[1] Before the introduction of boroglyceride I employed a five-grain solution of chlorate of potash, which was less efficient.

Clinical Lecture
ON
FUNCTIONAL DISEASES OF THE LIVER.

BY SAMUEL FENWICK, M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

GENTLEMEN,—We know perhaps less of the functional diseases of the liver than of those of any other structure in the human body of equal importance. The organ is popularly supposed to be very frequently deranged; but, from the changes its secretions undergo before they come beneath our notice, we have no means of proving how far such an opinion is correct.

Many years ago I commenced some inquiries in order to ascertain if any of the secretions afforded a means of testing the manner in which the hepatic functions are performed. For this purpose I first examined the colouring matters of the urine, but was unable to arrive at any definite conclusions, although no doubt in many cases there is a close connexion between the state of the urine and the condition of the liver. Observing the yellow coating which is so frequently present on the tongue in affections of the biliary system, I separated the colouring matter from the saliva in cases of jaundice. The material thus obtained seemed to be a derivative of the bile; but it was only present under certain conditions, and I was forced to abandon the hope that it could be employed as a test for the quantity or quality of the hepatic secretion.

You are aware that a bitter taste in the mouth is occasionally complained of by patients suffering from jaundice, and also sometimes by those who are only what is termed "bilious." I failed in various cases of jaundice to obtain evidence of what has been often surmised—viz., that the bitter taste is the result of the excretion of the biliary salts by the salivary glands. However, an elderly medical man consulted me, whose only complaint was an intensely bitter taste in the mouth. He never had suffered from jaundice, and he believed himself in other respects to be in perfect health. He found the taste increased after taking alcohol in any form, but no treatment he had adopted had relieved him. I received from him a considerable quantity of saliva, and obtained from it the ordinary indications of the presence of biliary salts. On thinking over his case, it seemed to me that if the salivary glands were capable of separating the biliary salts, perhaps some material derived from these might be a normal constituent of their secretion. The

Digitized by Google

sulphocyanide suggested itself to my mind, and I determined to ascertain, if possible, whether the quantity of this substance varied in different persons, and under what circumstances such variations occurred. The estimation of the sulphocyanide was, however, a matter of no small difficulty, for it is normally present in so minute a quantity that any attempt to isolate it appeared hopeless. You are aware that the addition of a persalt of iron to saliva gives the blood-red colour of sulphocyanide of iron, and it appeared to me that the simplest way would be to compare the depth of the colour thus produced in the salivas of those suffering from disease with that of persons in a state of health. The saliva of each person examined was therefore collected as it flowed from the mouth for about two minutes, and seven drops of a solution of half a drachm of perchloride of iron to one ounce of water were added, and the colour thus obtained was compared with a scale of colours prepared in the following manner:—A quantity of saliva was collected from a number of healthy persons, and the tint produced by the addition of the perchloride of iron was taken as the normal amount; a portion of the same saliva was then evaporated to one-quarter, and another to half, its bulk, and the colours produced in these respectively were assumed to represent four times and twice the normal amount of sulphocyanide; whilst two other portions diluted with water to twice and four times their amount were taken as representing half and a quarter of the normal quantity of the salivary salt. These were then copied in colours by an artist, so that there should be no variation in the tints.

In this way I examined during the course of many years the salivas of numerous persons who consulted me for different maladies, recording also the symptoms of which they complained, and in most cases the results of the treatment adopted. These observations were so numerous (probably many thousands) that I selected for analysis only those in which the amount of the sulphocyanide was much below or much above the normal. I have described these in this lecture as "private cases" whenever I have found it necessary to quote them. In order to check these observations, I requested Dr. Needham, at that time house-physician to this hospital, to examine in the same way the salivas of a number of patients who were under treatment in the wards, and two years afterwards a similar inquiry was carried on by Dr. Bedford Fenwick. The cases thus obtained, numbering between 200 and 300, were analysed together, and I have quoted them as "the earlier hospital cases." Although the conclusions from both of these sets of cases were generally in accordance with each other, there were numerous discrepancies which could not be explained. I therefore commenced a fresh series, in the following manner:—A solution of sulphocyanide of iron was prepared of definite strength, and was graduated by successive dilutions, so that each was only one-quarter of the strength of that above it. These were placed in the small flat bottles used by spectroscopists, each bottle being of equal thickness. I took my own saliva, which agreed in colour with that formerly taken as normal, as the normal standard, and the bottles were labelled + or −, according as they differed from N. Each of the salivas, when examined, was mixed with a definite quantity of the tincture of perchloride of iron, filtered through cotton wool, and being placed in a spectroscopic bottle of equal thickness was carefully compared with the graduated strengths of the sulphocyanide of iron.

In this manner I examined week by week the salivas of 500 patients admitted into my wards, carefully recording the depth of colour at every observation, but not looking at the notes of the cases in the hospital books. After all these persons had been discharged, I compared the state of the saliva of each in every week of his residence with his condition at the time his saliva was obtained. The results of these observations form the facts from which I have drawn most of the conclusions I am now about to lay before you, and I have quoted these as the "later hospital cases."

Before commencing our inquiries it is necessary to determine what is the normal amount of sulphocyanide in the saliva of healthy persons. No doubt this must vary considerably according to the circumstances of the individuals examined, but I thought we should obtain the best standard for reference if the observations were conducted upon persons of the same class as our hospital patients. I therefore procured the salivas of forty-three persons, most of the females being hospital nurses and the males either hospital porters or patients suffering from some trifling local malady, such as gonorrhœa. The following table shows the results of this inquiry:—

TABLE I.—*Showing the Colour of the Saliva of 43 Healthy Persons.*

Colour of saliva.	Males	Females.	Totals.	
− 1½	1	0	1	
− 1	2	2	4	6
− ¾	1	0	1	
− ½	4	5	9	
− ¼	2	0	2	
N	12	4	16	31
+ ¼	1	0	1	
+ ½	2	1	3	
+ ¾	0	0	0	
+ 1	2	0	2	5
+ 1½	1	1	2	
+ 3	1	0	1	
Totals...	29	13	42	

You will observe that the largest number of the salivas presented the depth of colour we before took as the normal standard, but that most of the females were half below it, and that thirty-one out of the forty-two were within half below or above that amount, only five being above and six below. It will be necessary that this should be borne in mind when we afterwards discuss the diseases to which persons apparently healthy, but in whose salivas the sulphocyanide varies greatly from the normal point, are especially liable.

In commencing an analysis of the cases in which the amount of the sulphocyanide in the saliva was determined, let me first direct your attention to the patients who were admitted suffering from typhoid fever. Thirteen are recorded in the "later hospital cases," all of whom recovered, and in each, as soon as convalescence was established, there was a sudden rise in the amount of the salivary salt, which either increased or was maintained at about the same strength until the patient was dismissed. This is seen in Table II., in which are placed in the first line the average quantities of the sulphocyanide in each week before and after the commencement of convalescence, and in the second the number of cases from which the averages were obtained. The date of convalescence was in each fixed at the day on which the temperature permanently fell at or below the normal point, and you will observe that in the second week before this period the average amount of the salt was only +¾. But during the febrile condition there is a very scanty secretion of saliva, so that the quantities we were able to obtain were very small, and consequently in a state of great concentration. It is evident, therefore, that the amount of the sulphocyanide daily excreted must have been very minute whilst the fever was going on, but as soon as this began to subside the average rose to +2, and remained high until the seventh week after the commencement of convalescence. Let me remind you that the figures in this table are averages, for in some cases the quantity rose to +4, and in some instances to seven times the normal amount.

The degree of increase of the salt seems to depend on the length of the febrile stage. In Table III. I have included in the first line all those in whom the fever lasted less than twenty-one days, and in the second those whose febrile stage exceeded three weeks in duration. It would appear from these figures that in cases in which the fever has been of short duration the increase of the salivary salt takes place more slowly, but the duration of the convalescence is longer than in those in which the febrile stage has been more prolonged. It is also worthy of remark that the greatest amount of secretion was reached earlier in the latter than in the former, the maximum being in the third week in the second group, and in the fourth week in the first group. If further investigations should confirm these conclusions, we shall have in the quantity of the sulphocyanide during the first week of convalescence a means of ascertaining the probable length of the period during which the patient is likely to regain his former health and strength. The augmented quantity secreted is not the result of an increased supply of food, for, as you are aware, the patients are confined to a liquid diet for two or three weeks after convalescence has been established. It is also worthy of observation that in Table II. the salt is seen to increase before the fever has quite subsided, so that the

Digitized by Google

state of the saliva may be of value as an indication that the febrile action is about to terminate.

Let us now ask ourselves what are the changes that occur during the progress of typhoid fever. Every day's observation shows you that there is a rapid loss of flesh and strength; the muscles quickly waste and the fat is absorbed, so that in a case of long duration the patient is reduced almost to the condition of a skeleton. As soon, however, as the fever disappears nature begins to repair the damaged structures, the appetite becomes keen, the digestive organs are stimulated into a state of unusual activity, and the patient day by day increases in weight and strength. What, then, I wish to draw your attention to is the fact that along with this unusual activity of the organs engaged in nutrition we find an excessive quantity of the salivary salt—a fact sufficient to indicate that, instead of its being a mere accidental result of local decomposition, as some have supposed, the sulphocyanide is in some way dependent upon the action of the digestive or assimilating structures. But, in addition to this, Table III. seems to point out that there is probably some relation between the quantity of the sulphocyanide secreted and the degree of activity of these organs, for it will be remarked that in the group in which convalescence was most rapid the amount of the salivary salt was the greatest.

A similar state of the saliva may be occasionally observed when from other causes there is a sudden demand made on the nutritive organs. In some cases of hæmorrhage occurring in persons whose digestive organs are not impaired the salivary salt will be found in increased quantity, at the same time that the loss of blood is being rapidly replaced. Thus a woman, about thirty years of age, was admitted into the hospital in a very exhausted condition. A few days previously, when she appeared to be in perfect health, she had suddenly fainted, and shortly afterwards had vomited a large quantity of blood, the hæmorrhage being repeated twice in the next few hours. There was no return of the bleeding from the stomach, but the general nature of the malady was shown by hæmorrhages being present in the retinæ. Two weeks after the attack the sulphocyanide was $+2\frac{1}{2}$, next week $+3$, and in the successive weeks $+3$, $+2\frac{1}{2}$, and $+1\frac{1}{2}$, at which latter date it is noted in the case-books that she had quite regained her strength and colour. One month afterwards she was again attacked in the same manner, and was readmitted in a very blanched condition; the amount of the sulphocyanide was remarked to be $+2$, and continued at that amount until she regained her colour and left the hospital.

The conclusion that seems fairly to follow from these facts is that an unusual amount of the sulphocyanide presents itself in the saliva whenever the necessities of the system call for an increased activity of the digestive organs; and this is supported by the circumstance that persons who are unusually stout and well fed ordinarily secrete a saliva having an excess of this salt. But you will naturally say, Is there not a necessity for an increased action of the assimilating organs in typhoid from the first moment when the patient is smitten with the fever? Certainly there is; but the nutritive organs are incapable of responding to the demand, for they themselves rapidly waste and lose their functional powers. Thus in four cases that had died of typhoid fever I carefully scraped off the whole of the mucous membrane of the stomach and found that the average weight was only 580 grains, whilst the average weight of the gastric mucous membrane in seventeen males who had died of other diseases was 1035 grains, showing that in this malady the stomach loses nearly half its bulk. Nor is there merely a loss of bulk; there is also an impairment of functional activity, for in seven cases I made an artificial gastric juice with the mucous membrane of the stomach, and found that the average amount of coagulated albumen dissolved was only one grain, whilst the amount ordinarily dissolved by the mucous membrane of the stomachs of persons dying from other disorders was four grains. In two of the typhoid cases the albumen was quite unaffected by the artificial gastric juice, and in one a small quantity only was dissolved. It is therefore probable that in typhoid the general wasting of the body is the result not only of an increased destruction of tissue, but that it also arises from the inability of the digestive organs to supply sufficient nutriment to compensate for the augmented waste; and, as we have already seen, along with the diminished activity of these organs there is a decreased quantity of the sulphocyanide in the saliva. As soon, however, as the blood-making organs are restored to activity the salt reappears in the salivary secretion in an increased amount.

It will be obvious that, if the above conclusions are correct, we should find the quantity of sulphocyanide below the normal whenever the digestive organs are unable to supply nutriment sufficient to meet the requirements of the system. Let us, then, test this by the condition of the saliva in maladies attended with rapid loss of flesh. Perhaps one of the best diseases we can select is pulmonary phthisis. Seventeen cases are recorded in the "later hospital records," of which ten died or were removed from the hospital in a sinking condition, and seven were dismissed much improved. Of those who died, the average amount of sulphocyanide was only $-1{\cdot}27$, and in some no colour at all could be produced by the addition of the solution of iron to the saliva, so that in these we may assume the secretion of the salt had ceased. In only two of these was the amount above the normal—in one it was $+\frac{1}{2}$, in the other $+1$; but in all the others it was much below the ordinary quantity. In eight of them the weight of the body was regularly recorded; in five there was a diminution of weight, and these exhibited an average of $-1{\cdot}15$ of the sulphocyanide. You must not, however, suppose that this condition of the saliva is an indication of the existence of tubercular disease; it is only a concomitant of a failure of the general nutrition, for the

average of those who improved in the hospital amounted to +1·; only two exhibited a deficiency of the salt, and all the others showed an amount above the normal. In three there was a weekly gain in weight, and in these the average quantity of the sulphocyanide was above the normal. The above facts are supported by the "earlier hospital cases," from which it appears that the diminution of the salivary salt increases with the duration of the malady. Thus twenty-six cases of phthisis are recorded, of whom 25 per cent. had a deficiency of the sulphocyanide when examined within six months of the beginning of the illness, whilst 58 per cent. of those between the sixth and twelfth months, and no less than 87 per cent. of those above twelve months' duration, presented the same condition.

A similar deficiency of the salivary salts is usually observed in the later stages of malignant diseases. In almost all of those in which the stomach was the seat of cancer the sulphocyanide became deficient at an early period, and remained so until the termination of the case; thus I find eight cases recorded of this disease, and in all the amount was very small or was entirely absent. When other organs were affected by cancer, the period at which the sulphocyanide sank below the normal varied with the rapidity of the growth, the organ involved, and the more or less rapid inroad made upon the general health of the patient. This fact may perhaps prove useful in the diagnosis between cancer and simple ulcer of the stomach. It is rare to find a deficiency of the sulphocyanide in the latter, for the power of digestion usually remains good, and in cases of hæmorrhage, as we have before seen, there is often a sudden increase in the quantity; whereas in cancer the amount early falls below the normal from the loss of digestion with which it is accompanied. But you may ask, Why is there such an early failure in the general nutrition in gastric cancer? In every case that I have examined microscopically changes of an important nature have been found in the mucous membrane of the stomach, although it often appeared normal to the naked eye, and the parts examined were at a distance from the seat of the tumour. The peptic glands were either closely adherent to each other or were in a state of atrophy, and an infusion of the mucous membrane exerted only a slight power of dissolving coagulated albumen. In addition to the structural changes, the patient's strength is sapped by the more or less constant discharge of blood, by frequent vomitings, or by an obstruction to the passage of the food into the intestines.

From the above facts, we are bound, I think, to conclude that whenever an unusual demand is made upon the nutritive organs of the body by the necessities of the system, and the patient gains flesh and strength, the sulphocyanide in the saliva is found to be increased in quantity; but when, on the contrary, a person rapidly wastes from some general disease the amount of the salt is diminished. An increased quantity of the sulphocyanide, therefore, under such conditions, manifests an excess of the income over the expenditure, whilst its diminution points to an excess of the expenditure of the system over its income.

We before found that when, as in convalescence after typhoid fever, an increased activity in the cell growth of the whole body took place, there was an unusual amount of the sulphocyanide in the saliva, and we attempted to explain this by supposing that the necessity for repairing the previous waste of the tissues stimulated the blood-forming organs into increased activity, the augmented amount of the salivary salt being only an indication of their increased action. But if there is a relation between the necessities of the system and the activity of the blood-making organs, we should expect that an increased local cell growth would act in the same way as when it is general, and would stimulate the functional activity of the nutritive organs, and that consequently, under such circumstances, the amount of the sulphocyanide would be also augmented. Let us, then, test the truth of this anticipation by the examination of the saliva in persons who were suffering from increased local cell growth—in other words, from malignant or inflammatory affections.

We have already seen that in most of the cases of cancer the salivary salt has been below the normal, but in these the local malady had made great inroads upon the general health. Where, however, either from the position of the tumour or the slowness of its growth, there was no marked cachexia, the sulphocyanide was above the normal. Thus, in a case of sarcomatous tumour of the ribs the amounts registered each week were +2¾, +3¼, +2¾, +3¼, +3¼, and the patient left the hospital with no loss of weight or strength, although the size of the mass had greatly increased. I have met with the same circumstance in some cases of cancer of the liver, where the disease was in an early stage, and where the growth was rapid, although there was in some of these also jaundice, probably resulting from compression of the smaller bile-ducts. In the earlier stages of phthisis there is usually an increase in the salivary salt, and it is not until the patient has been reduced by diarrhœa, vomiting, or loss of appetite that the diminution we before observed presents itself.

But you may naturally object that in typhoid the increase of the sulphocyanide was only observed after the cessation of the fever, whilst in cancer and phthisis it takes place during the progress of the disease. This is easily explained when you remember, what was before stated, that in typhoid there is but little digestive power, so that the blood-making functions cannot respond to the demands of the system until after convalescence has set in; whilst in the local maladies we have been just considering the digestive functions appear, in the earlier stages at least, to be intact.

In most cases of acute inflammation there is a rapid local cell growth. What, then, is the state of the saliva under these circumstances? Let us first look at acute pneumonia, of which disease there are nine instances recorded in the "later hospital cases." The average amount of the salivary salt in these was only +·95; they were examined after convalescence had set in, for unfortunately I have no records of the state of the saliva during the acute stage. The smallness of the increase is what might have been anticipated, for everyone must have observed how little flesh the patient loses in an ordinary attack of acute lobar pneumonia, and how rapidly he regains his strength. This is supported by the fact that the more severe the case was, the greater was the amount of sulphocyanide during convalescence. Thus five were dismissed within three weeks, and their average was +·70; four required a longer residence to regain their strength, and their average was +1·27.

Bronchitis, when uncomplicated with heart and kidney disease, seems to have no effect on the production of the salivary salt, for in seven cases which were examined from week to week the average did not exceed the normal.

In acute pleurisy there is a considerable cell growth, and consequently we find a marked difference in the amount of the sulphocyanide from that in bronchitis. There were thirteen observed in the "later hospital cases," four of which presented only the physical signs of "dry pleurisy"; in seven there was exudation of fluid, and most of these were treated by aspiration. In the cases of dry pleurisy the average of the salivary salt was +1·09; in those accompanied by effusion it reached +1·45. A similar result is afforded by the "earlier hospital cases"; for of nine cases, four were examined within one week of the commencement of the illness, and three of them presented an excess of the sulphocyanide, while in one it was normal; three were examined between the second and third week, of whom two had an excess and one was subnormal; after the third week two were examined, and both were below the normal. It is therefore evident that the amount of the salivary salt is greatest where there is most local cell growth, and it often falls below the normal in the stage of absorption. There were two cases of empyema in the "later hospital cases," both treated by drainage, and the examinations of their salivas are very interesting. The weekly amount of the salivary salt was in one +2½, in the other +3½; but in each at the twelfth week of the illness it fell suddenly—in the one to −¼, in the other to −½, and in each it remained in amounts varying from −1· to +½ till the termination of the illness.

Observation teaches us that a local cell growth, whether malignant, tubercular, or merely inflammatory, will often continue for a length of time without perceptibly reducing the strength of the patient, the undue loss of material being supplied by an increased action of the nutritive organs; but that when a certain point is reached the general health rapidly deteriorates. This point—probably that at which the expenditure exceeds the income of the body—seems to be accurately marked by the sudden diminution in the quantity of the sulphocyanide.

Two cases of "granular kidney" were admitted suffering from uræmic convulsions; both improved under treatment, and the amount of the salivary salt increased in proportion to the improvement. One had, on his admission, +1, which increased to +3, at which figure it still stood on his leaving

Digitized by Google

the hospital at the end of eight weeks. The second had only $-\frac{1}{4}$ at first, but it had risen to $+2\frac{3}{4}$ on the fifth week of treatment. In another case it was normal on admission and remained so the next week, but ten days afterwards he died with uræmic symptoms, no other observation being recorded in the meanwhile.

In chronic tubular nephritis, there must be a large demand upon the nutritive organs to supply the waste caused by the abundant cell growth and the drain of albumen from the diseased organs. Consequently I have generally found that in the early stage the amount of sulphocyanide was above the normal, and remained so until the patient's strength began to fail. In one case of this kind it was $+1\frac{1}{2}$ on admission, but it rose to $+2\frac{1}{2}$ the next week, and remained high until he left the hospital much improved. Two cases died; in one the quantity was at first normal, but it sank next week to -2, and remained at this point until death; in the other it was at first $+1\frac{1}{2}$, but it had fallen to $-\frac{1}{4}$ on the last observation recorded before his death.

(To be continued.)

REMARKS ON

CEREBRAL ABSCESS DUE TO DISEASE OF THE TEMPORAL BONE, AND ITS TREATMENT.[1]

BY ARTHUR E. BARKER, F.R.C.S.,

SURGEON TO UNIVERSITY COLLEGE HOSPITAL AND TEACHER OF PRACTICAL SURGERY AT UNIVERSITY COLLEGE.

IF surgeons were only called upon to deal with cases of abscess of the brain when physicians had determined their locality, our position would, in my opinion, be clear, and our task, as a rule, a light one. For I am one of those who hold that in these days of aseptic surgery those areas of the brain in which inflammatory foci are most commonly met, and which are well known from experience to be wondrously long-suffering, may be as freely dealt with almost as the structures external to the skull. But far more than mere operative treatment of these conditions is demanded of the surgeon now, and he can only be really useful and reliable when he has studied the whole subject of the pathology and clinical symptoms of cerebral abscess with as much care as that of the details of surgical procedure

The mode, however, of approaching this study must be very different to that hitherto adopted before we can hope for much practical result from it. No one who at the present day reads through the abundant literature of cerebral abscess can fail to be struck with the tendency there has been in the past to consider abscess in the brain as one disease, whereas in reality it is only a sequela or accident occurring in the course of a long series of totally distinct ailments. Cases have been grouped together which have no possible affinity, and the result has been much confusion. What possible pathological relation, for instance, is there between an abscess due to commotio cerebri and one the result of septic phlebitis from middle-ear disease? and yet we find in those collections of cases which have hitherto been appealed to for information on the subject results produced by these and other most widely-differing causes grouped together as if they all belonged to the same disease because they affected the same organ. Let me enumerate some of these causes of abscess in the brain produced without external breach of surface to help diagnosis. 1. Bruise of the brain under a spot of the skull which has received a sharp blow, but where the bone is uninjured. 2. The spread of inflammation into the brain along a vein leading from a portion of bone damaged by a blow. 3. Commotio cerebri, the result of contrecoup. 4. Secondary infarcts in general pyæmia. 5. Disease of the lungs. 6. Hepatic inflammation. 7. Caries of the bones of the nose. 8. Disease in the middle ear.

Now, as long as cerebral abscess was considered an inevitably fatal condition, and the only questions involved were the diagnosis of its presence and the prognosis, such a wholesale method of dealing with the subject may have seemed to some sufficient. But now that the brain has been brought within the reach of operative surgery by the perfecting of antiseptic methods much more is demanded, and above all knowledge to enable us to fix the locality of the inflammatory focus. For this knowledge in the case of that class of cerebral abscess to which I shall confine my remarks—namely, that due to disease of the temporal bone—I am afraid we shall have to wait a long time if we rely *solely* upon special clinical symptoms. It appears to me that we are likely to learn far more facts available for localisation and treatment from a careful study of their pathology, macroscopic and microscopic, than from a search after special nerve symptoms. But if this is to be true, one of the most indispensable conditions of our research into their nature must be kept in view—namely, that we shall separate and keep apart those abscesses which depend upon totally different exciting causes and study each for itself according to its own special etiology. Strongly impressed with this idea, I shall confine my remarks to matters relating to one particular form of cerebral abscess which is of relatively frequent occurrence, and for which surgical treatment will probably be most frequently necessary for a long time to come. I refer to abscess depending upon inflammation of the temporal bone. Thus limited, the field is still a large one. I find, by combining Rudolph Meyer's tables with those of Dr. Ogle, that we have 101 cases of abscess of the brain classed as to cause, and 18 unclassed. Of these 101 classed, 29 were due to disease of the temporal bone following upon suppuration in the middle ear. Traumatic causes followed next, with 27 cases; then suppuration in the lungs and liver, with 20 cases. Among the remaining 24 cases pyæmia was credited with 7, the rest being made up in various ways. Now, although I should not like to rely too much upon these statistics, which were compiled twenty years ago, when pathological observation was not so accurate as now, I believe they are sufficiently accurate to enable one to estimate roughly the relative frequency of abscess due to ear disease as contrasted with those from other causes. And I think, from a study of the tables referred to and of other cases as well, that a revision of the question would now lead to ear disease being credited with a still larger relative number of cerebral abscesses than above, and that 30 per cent. of all causes would be below the mark. It would probably be nearer 50 per cent., pyæmia having now become a relatively rare affection, and fractures of the skull, or suspected fractures, being now treated by antiseptic surgeons in such a way as greatly to reduce the number of traumatic abscesses of the brain. At the same time, I question strongly whether a corresponding improvement in the treatment of suppuration in the middle ear has yet taken place generally to largely reduce the mortality from ear disease. It is to this large group, then, and to it alone, that the remarks I have to make refer.

The pathology of encephalic abscesses due to ear disease is not very abstruse. They appear (broadly stated) to be produced in two different ways, of which it is hard to say which is the commonest. In the first place, we find a septic phlebitis extending from the walls of the tympanic cavity into the substance of the brain by a longer or shorter route, and there setting up an inflammatory process in the white substance. Here the dura mater of the petrous bone may show but few signs of disease, and the serous covering of the encephalon be perfectly normal to the naked eye; there may even be a considerable thickness of sound cortical brain tissue between the arachnoid and the cavity of the abscess. The course of the veins along which the inflammation extends is liable to considerable variation. In the case of the brain they usually pass from about the middle of the temporo-sphenoidal lobe either into the superior petrosal sinus or to the dura mater about the roof of the tympanum, or to the petroso-squamosal suture. The abscess in the brain consequently is set up by "a retrograde phlebitis." The next mode of origin is that of simple extension of the inflammation from the middle ear to the dura mater, and from this to the cortex of the brain directly through the medium of a more or less localised septic lepto-meningitis. This last mode of origin is, I think, more often met with in the case of the cerebellum, the last in that of the brain. Both may start from the same form of inflammation in the middle ear, with or without caries of its walls and with or without subdural abscess. It is obvious that the last mode of origin is associated with the gravest local condition. In the first place, septic meningitis has a great tendency to become general; and, next, such an inflammation

[1] Read at the discussion on Cerebral Abscess at the Medico-Chirurgical Society of Glasgow, Feb. 11th, 1887.

Digitized by Google

can hardly spread backwards towards the cerebellum without involving the lateral sinus and producing more or less septic phlebitis in it, with or without general pyæmic infection. Moreover, subdural abscess may produce grave symptoms.

But though the pathology of encephalic abscess from disease of the temporal bone may be a comparatively simple study in the dead body, in the living the study of the process is fraught with difficulty. For it is plain that the same form of disease in the bone may produce at least five distinct conditions of grave disease. These are (1) general septic meningitis; (2) plastic phlebitis of the sinuses; (3) pyæmia, generally associated with phlebitis of the sinuses; (4) abscess of the cerebellum; and (5) abscess of the cerebrum. Moreover, each of these may be met with not only alone, but grouped together with one or more of the others. Here, then, is the great obstacle to our dealing with abscess in the brain or cerebellum by operation—viz., the difficulty of differentiating them during life. For to operate on an abscess of the brain or cerebellum where general septic meningitis or pyæmia is present would be almost hopeless; and to open an abscess in the cerebellum while another is left untouched in the brain, or *vice versâ*, would not be successful surgery. Again, to leave unrelieved a condition of the temporal bone which has started and is keeping up a phlebitis of the lateral sinus, and may at any time end in general septic infection, while the accidental brain abscess is opened and drained, is not likely to lead to good results. There is a sixth condition which has much in common with those last mentioned, both in pathology and clinical symptoms. This is the simple accumulation of pus in the middle ear, due to blocking of the external meatus by swelling or polypoid granulations. Now, any or all of these six conditions may follow upon the simplest attack of suppurative otitis media. Is it possible to distinguish them clinically one from the other? I think it is to a large extent, to anyone who has studied the pathology of this whole group of affections as a whole, commencing with the initial inflammation of the tympanum, and has closely watched their course in the living. It will not do to know all about intracranial abscess and the varieties of meningitis and neglect the study of the initial affections of the middle ear, which require just as close attention.

For brevity's sake I will now venture to sketch roughly and without argument the method I should pursue in a case where suppuration in the middle ear was followed by grave constitutional disturbance, arousing a suspicion of brain disease. In doing so I shall endeavour to embody in the sketch the rules I have found useful in dealing with a large number of such cases. If called to treat a patient who, having recently had severe pain in the ear for the first time, had begun to suffer from violent headache on that side, drowsiness, rise of temperature and quickening of pulse, with or without rigor and delirium, the surgeon, knowing that the commonest cause for these symptoms is pent-up pus in the middle ear, would at once examine the latter with a speculum and a good light. If the membrana tympani were seen to be bulged outwards by a quantity of opaque white pus, he would incise it from top to bottom behind the malleus and transversely below the latter. If pus ran out freely, the symptoms would probably all shortly disappear. If they did not do so after the tympanic cavity had been freely drained and cleansed, but the headache became worse and the temperature and pulse remained high, while further examination disclosed optic neuritis, and the patient began to have the "cephalic cry" and so-called cervical opisthotonos, acute meningitis would be suspected. If after incision of the membrana tympani and thorough drainage the headache and dulness disappeared, but the temperature kept oscillating between the two extremes without any approach to regularity, while occasional rigors developed, we should suspect and probably soon recognise pyæmia with its secondary manifestations. In neither of these cases would there be any probability at the outset of abscess either in the brain or cerebellum. After such recent, acute attacks, while meningitis and pyæmia are not uncommon, abscess in the encephalon is almost unknown. Subdural abscess and plastic phlebitis are also unlikely to occur in these cases of early acute disease. But if a discharge from the ear had been present for a long time, and had lately ceased with the onset of the above acute symptoms, the most common cause would be blockage of the meatus with polypoid granulations or œdema of the passage. In the first case immediate relief ought to follow removal of the growths. In the second, if marked, or, should the symptoms persist after removal of the polypi, an opening should at once be made into the mastoid antrum, and the middle ear be drained from this until the meatus had been rendered again pervious. This operation ought always to be done in doubtful cases as an aid to diagnosis. It is as simple and devoid of risk as it is useful. Moreover, as a preliminary to graver operations on the brain or cerebellum, it has the great advantage of enabling us to cleanse the foul infecting focus in the middle ear, and to continuously drain it. But though by this drainage of the middle ear we should have eliminated one source of uncertainty, the symptoms might still persist. If so, in a chronic case, we should have to consider the possibility of the presence of encephalic or subdural abscess, or phlebitis of the sinuses, even though meningitis and pyæmia had been already excluded.

Now as to subdural abscess. Is it possible to diagnose its presence in an early stage? I think hardly with certainty, unless by exploratory operation, though there may be good grounds for suspicion from general considerations. In the first place, subdural abscesses are, as a rule, only found in very chronic cases, and in those where matter has been pent up in the temporal bone, not where the discharge has been free. They are usually heralded by a single rigor, with rise of temperature, which does not oscillate much if uncomplicated by pyæmia. The patient will be heavy and dull, only complaining of aching in the temporal region. The pulse will be rapid, unless the abscess be large enough to produce compression, which is not common. It seems probable that this condition may produce optic neuritis, but further observation is required on this point. An examination of the mastoid and squamosal portions of the temporal bone may reveal more or less tenderness and œdema, which will, if present, persist even after free drainage of the middle ear as above. These symptoms all point to an inflammatory focus close by, probably pent-up matter, and, as our preliminary operation has shown that it is not in the middle ear or mastoid antrum, we must look for it under the adjacent dura mater. But at what point is the pus to be looked for? The study of the disease in the post-mortem room teaches us that it will be found either over the roof of the tympanum close to the squamoso-petrosal suture, or on the posterior surface of the petrous bone—i.e., in the groove for the lateral sinus. In some cases it extends from one to the other of these spots. If in the first situation, it is reached by cutting cautiously through the bone layer by layer with a gouge at a point about half an inch above and the same distance behind the centre of the bony meatus of the ear. If in the second position, the collection is found half an inch directly behind the centre of the meatus. With due care the dura mater can be exposed in both situations with very little risk. We cannot be certain of the non-existence of a subdural abscess until both spots have been examined, but the higher operation should be done first, then the lower. The state of the bone, too, in both situations must be very carefully examined as it is cut away. If pus underlie it, it is usually spongy, and the matter will begin to ooze through its pores before the abscess is actually reached, as was found in two of my cases. If no pus be found, and the high temperature and other symptoms persist for many hours after the operation, the case will probably turn out to be one of phlebitis of the sinuses with septic absorption or sapræmia as distinguished from pyæmia or general septic infection, which is almost certain to be accompanied by rigors, a greatly oscillating temperature, and secondary suppurations in distant parts. For this condition little can be done beyond what has been already effected by the exploratory operations—namely, thorough cleansing and drainage of the initial focus of suppuration; but this is a great deal. If actual thrombosis of the lateral sinus and internal jugular have taken place, there may be a flush on the same side of the face and injection of the conjunctiva, together with deep-seated induration over the track of the internal jugular vein. This could be well felt in one of my cases. Optic neuritis may also be well marked in cases of phlebitis of the lateral sinus, as was seen in two cases on which I operated for what I believe to have been this condition. Both patients rapidly improved after operation, and are now well, all traces of the optic neuritis having disappeared.

I have briefly traced these four consequences of middle ear suppuration in the order of their frequency and pathological sequence. It is necessary to be thoroughly familiar with them and the way to eliminate one after the other, before we can hope for anything approaching a safe diagnosis of abscess in the brain or cerebellum.

Digitized by Google

Turning now to the latter conditions, our first question is: What probability is there of their occurrence? It is quite plain, in the first place, that abscess of the encephalon is far less common than the other affections just described, the symptoms of which so often arouse the suspicion of the presence of the latter condition. I feel sure, from personal observation, that pyæmia, meningitis, phlebitis of the sinuses, and subdural abscess are, broadly stated, ten times more common than abscess of the encephalon. Then, again, the more extensive the destruction of the walls of the tympanum the more likely is the latter to be produced. This is almost as much as to say that the more chronic the bone disease the more likely a brain abscess, but not quite. It is better to say, the more imperfect the drainage from the middle ear in chronic cases the greater the probability. For disease lasting a year or two, in which the meatus has been blocked by granulations or swelling will be far more likely to lead to abscess of the brain than the same amount of disease lasting twenty years where free drainage existed. The history, then, of a case of otitis media purulenta will help us much in estimating the likelihood of the presence of cerebral abscess. Again, it requires far more extensive mischief in the walls of the tympanum to produce a cerebellar abscess than one in the cerebrum. Here, again, the history of the case and an exploratory operation are of the greatest assistance. From an analysis of cases which I have made it appears that abscess of the brain is a much more common sequela of disease of the tympanum than abscess of the cerebellum. I find that out of forty-five cases only twelve of abscess in the cerebellum were found against thirty-three in the cerebrum. This is but a rough calculation, but from personal observation and reading I feel sure it is near the truth. The brain is about three times as liable to abscess as the cerebellum.

Now, what does pathology teach us as to the region of the brain in which these inflammatory foci are found. This, namely, that they are most usual in the middle or posterior part of the temporo-sphenoidal lobe? I think that nine-tenths of them would be found to lie within a circle with a three-quarter inch radius, whose centre lay an inch and a quarter above and the same distance behind the centre of the bony meatus of the ear. This, then, might be described as the dangerous area, and as it fortunately also includes the spot indicated above as most likely to be the seat of subdural abscess, from the same cause an exploration for the latter would be a necessary preliminary to a trephining operation for cerebral abscess. As to the position of abscess in the cerebellum, it is, I believe, always found at the outer and anterior part of the lateral lobe which rests against the petrous bone. If these conclusions be justified, we have much valuable evidence to go upon as operators. We know in the case of the brain where to look for abscess, a point we are not likely to learn from any special symptoms, inasmuch as in collections of ordinary size the affected tissue would be quite outside the motor areas, and would belong to a part of the brain very tolerant of stimulation, and whose functions are still obscure. This last point was well illustrated in the case of cerebral abscess in which I operated. Neither the movements of the silver drain tube within the temporo-sphenoidal lobe nor the injection of the cavity therein with boracic lotion seemed to have any effect upon the patient, even when he was perfectly conscious; nor did the scraping of the cortex during the operation produce any nerve symptoms. But though there may be no special nerve symptoms to guide us, there are other general clinical signs of great value. I need not enumerate these in detail to a society such as that I have the honour to address, but I should like to indicate briefly those which appear to me of special value.

First, there is the feeling of malaise and drowsiness with slow pulse terminating in a sudden great rise of temperature with a single rigor. Next, the gradual fall of temperature to *subnormal*, without perhaps any subsequent rise, the pulse remaining slow and full. There is one point in regard to this subnormal heat, which I noted in my own case, to which I should be glad to specially direct attention, as I do not find it anywhere alluded to. It may or may not prove of value in the future. It is this: the subnormal temperature was most marked in the evening. This is so unlike what we are accustomed to see with pent-up septic matter in other situations where an evening rise is considered characteristic, that it may have some special significance in cases of abscess of the brain. I have noted the same point in other cases.

Another symptom also noted in other cases of cerebral abscess was strongly marked in that under the care of Dr. Gowers and myself. This was *the sluggish but perfect cerebration*. When asked a question, for instance, the patient appeared to take no notice for several seconds, until one thought he could not have heard, or had forgotten that he had been addressed. But presently he would begin to answer slowly and deliberately, but with perfect intelligence. It was the same with his movements. This condition lasted for some days after the opening of the abscess in our case, and we noticed that after considerable improvement had taken place there was a relapse into slow talking, which appeared to coincide with an imperfect drainage of the abscess, the latter having been left undressed for a longer period than usual, and the drain tube being then found outside the skull altogether.

As to optic neuritis, I venture to think we must be cautious in relying on it as a sign of cerebral or cerebellar abscess. It certainly may be present in an intense degree where extensive disease of the middle ear exists without abscess in the brain or cerebellum. For instance, I have seen it in two cases (intense in one of them) in which opening up of the middle ear through the mastoid bone was followed by its rapid disappearance and the complete and permanent recovery of the patients. The condition here was probably phlebitis of the lateral sinus with subdural abscess. But of course, taken with other signs, optic neuritis is a valuable symptom.

Harley-street, W.

RESECTION OF AN IRREDUCIBLE AND GANGRENOUS INTUSSUSCEPTION.

WITH A CONSIDERATION OF THE TWO CHIEF METHODS OF TREATMENT: INFLATION AND ABDOMINAL SECTION.

BY LAWFORD KNAGGS, M.A., B.C. CANTAB., F.R.C.S. ENG.

(*Concluded from page 1126.*)

FROM the facts before mentioned it is impossible to avoid coming to the conclusion that forcible distension of the bowel, whether by air or water, is an operation never entirely devoid of danger; that in very young children it is one of very considerable risk; and that in all cases it should be employed with great judgment and care. But when rupture does occur, to open the abdomen at once is obviously the only hopeful course to pursue. The injury is by no means necessarily situated in gangrenous bowel, and, other things being satisfactory, there is no reason to despair of a successful result. In Mr. Symond's case, to which he has very kindly permitted me to refer, this was done and the rupture sewn up. The child, however, was too exhausted to rally from the operation, but at the necropsy the sutured bowel was able to resist successfully very considerable distension with water. To be of any avail operation should be immediate, and therefore it would be well, whenever possible, to have the necessary requisites at hand, in case inflation should prove disastrous or fail to effect reduction. The desirability of being able to recognise that reduction has taken place after inflation is obvious; for if a doubt exists, and further time is allowed to elapse, the dangers are very materially increased if reduction has not been accomplished.

What are the signs by which we can recognise successful reduction after inflation? To what fallacies are they open? Are they so sufficiently certain as to leave no reasonable doubt as to the result? Mr. Clement Lucas[1] publishing a successful instance, puts them down as follows: 1. The tumour gradually sinks away under the hand and is lost. 2. A gurgle of air is felt and often heard. 3. This is followed by sudden and uniform distension of the abdomen, which becomes tympanitic. But the history of cases shows that a tumour may not infrequently disappear after inflation, whilst its early reappearance proves that its reduction has not been complete. Dr. Goodhart has shown[2] that in consequence of the greatest congestion and swelling taking place at the apex of the invagination—the portion that is the last to be reduced—the final part of the reduction may be the most difficult, or even impossible. This fact no

Digitized by Google

doubt explains some of these cases, the invagination being reduced to so small a size as to escape detection, and the swollen state of the abdomen after inflation adding to the difficulty of the search. Other cases may perhaps be explained by the tumour becoming buried beneath distended intestine. If an invagination has reached the descending colon, it is obvious that the distension that occurs must be at first local, and as reduction goes on the swelling will mark the course of the descending and transverse colon. When the colon is entirely unravelled the swelling will become general, for I believe, and this case supports the view, that considerable distension of the colon is quite sufficient to produce uniform distension of the abdomen. Post-mortem evidence confirms this, for the small intestines may be quite concealed by a distended large bowel. If the intussusception is of the ileo-cæcal variety, or of the large intestine only, the chances are greatly in favour of reduction having occurred when this general distension takes place; but if the small intestine is the seat of the invagination, the disappearance of the tumour will probably only mean that the distended colon is pushed in front of it. The gurgle of air is not, I think, a symptom of great importance. If this reasoning is correct, cases will occur in which these symptoms will present themselves and the invagination still remained unreduced. Such a case is the one I have reported. In a case in which inflation recently proved successful in the hands of Dr. R. W. Brogden of Ipswich, with whom was associated Dr. Carrington, there was "an alteration from distinct hardness and contour to comparative softness and want of definition in the shape of the mass," but doubt existed as to the success of the treatment till it was set at rest by the disappearance of the other symptoms. The experience of other surgeons would, I believe, show that such doubts as to the success or non-success of inflation are by no means rare. When, as in Dr. Brogden's case, they are solved satisfactorily, all is well; but when, on the other hand, lapse of time proves the operation to have been futile, as in mine, what an amount of harm may have resulted, and how largely may the patient's chances have been prejudiced. I conclude, therefore, that cases will occur in which at the time of inflation the operator, if sure of the exact nature of the invagination, may feel certain that reduction has been accomplished. Yet there will be others in which doubt must exist as to the result until the disappearance or continuance of the symptoms, or the reappearance of the tumour, settles the matter.

The *position of the tumour* is a point of considerable importance in considering the probability of inflation proving successful, or in estimating the amount of good that it has effected. If it is in the descending colon, the invagination is almost certain to be one of the large intestine, or of the ileo-cæcal variety, and in the large majority of the instances of the successful employment of inflation or enemata that I have met with the tumour was stated to have been situated on the left side or felt per rectum.[3] If, however, the tumour is on the right side, or near the median line on the right side, there must exist considerable uncertainty as to its variety, and therefore disappearance of the tumour with distension of the abdomen must leave it doubtful whether the tumour has been disinvaginated or only obscured. Before leaving this part of my subject it is well to point out that sudden uniform distension of the abdomen is the most obvious sign that rupture has occurred. The expansion is so immediate and so general, so different from the more gradual uniform distension that takes place so long as the air is within the intestines, that it is impossible to remain in doubt as to the accident that has taken place.

There is no longer any question as to the desirability of opening the abdomen in these cases, but the time when it should be done can hardly be said to be generally agreed upon. In the hope of throwing some light upon this point, I have collected from American and English records thirty-seven cases in which abdominal section has been performed for intussusception. I am indebted for twenty-one of these to a paper by Dr. Sands in the *New York Medical Journal* (1877), and to Mr. Jacobson and Mr. Symonds for permission to include four cases that have not been published. In the first three successful cases the details are somewhat incomplete; but from the age of the patient and the duration of the illness, which [illegible], it is probable, in the absence of any direct statement to the contrary, that the operation was performed either before or very soon after acute symptoms had appeared. In the next four this is more definitely stated. In two acute symptoms never developed, and in two the operation was performed twelve and eighteen hours respectively after they had set in, whilst in the last a successful result was obtained after four days' acute symptoms, when the pulse had reached 200 in the minute, and when the child appeared so much exhausted that the operator "was doubtful whether much should be attempted for its relief." The moral of these cases is plain. Success is more certain to be obtained if operation is undertaken before acute symptoms set in, or, if they have set in, before many hours have been permitted to elapse. The last case is an eloquent encouragement to persevere when the prospect seems hopeless. (See Table I.)

TABLE I.—*List of Cases of Intussusception successfully treated by Abdominal Section.*

No.	Names of observers.	Sex and age.	Duration of symptoms.	Other points.
1	Velse, 1784	F., 50 years	Not stated	—
2	Fuschius, 1825	M., 68 years	10 days	—
3	Wilson, 1838	M., 20 years	17 days	—
4	Hutchinson, 1873	F., 2 years	1 month	Symptoms never acute.
5	Marsh, 1876	M., 7 months	14 days	Acute symptoms 12 hours before operation.
6	Howse, 1876	F., 33 years	18 days	Acute symptoms not developed.
7	Sands, 1877	F., 6 months	18 hours	Acute symptoms from the first.
8	Godlee, 1883	— 9 months	4 days	Acute from the first.

The duration of the acute symptoms in the list of unsuccessful operations (Table II.) bears a marked contrast to their duration in the successful cases. Where I have been able to state it definitely, they have existed, with one exception, from three to seven days; and, could I have ascertained it in the remaining instances, I believe the contrast would have been greater. But an inquiry into the cause of death is likely to help us as much as a comparison of the duration of acute symptoms. I assume, where I have found no cause of death stated, and where the patient has succumbed within a few hours after the operation, that exhaustion increased by the shock of the operation has been the chief cause of death. In those cases in which peritonitis existed, probably traceable to the operation, it would be but a small factor compared with the other two, and but for them might have been recovered from. Out of twenty-seven cases, no less than twenty-three died within twenty-four hours (twenty within twelve hours) from exhaustion and shock; and two others, though surviving into the second day, might possibly be included under this heading. Two only can fairly be excluded—one in which the child died of purulent peritonitis the result of the operation, and the other where a man survived nine days after an abandoned operation with a ruptured intestine and general peritonitis. If we are to improve our results we must eliminate shock and exhaustion. Where success has been attained, it has usually been when acute symptoms have lasted only a very short time, or before they have set in. Where operation has failed, acute symptoms have been in existence for some time. The exhaustion they produce has been often very marked, and in numerous instances the condition of the involved parts has necessitated either the abandonment of the operation or the performance of a purely palliative one, or the more severe but more scientific undertaking of removal of the damaged intestine. The more acute the symptoms, the more rapidly does exhaustion supervene; the greater the damage inflicted upon the bowel, the worse does the patient's state become.

To open an abdomen under ordinary conditions is not now regarded as an operation of very great gravity. It is done every day for conditions that are trivial compared to this form of intestinal obstruction, and its results become more encouraging with increasing experience. But to allow an intussusception to continue is a matter of most serious moment, and usually fatal. Notwithstanding this, our present attitude, whilst recognising that operation is the only measure that is sure of giving relief, is to wait until nothing seems left to us but operation; to wait until exhaustion is advancing at an increasing pace, and shock is almost certain to prove too great for success; to wait until to a simple abdominal section must be added the absolute necessity

[3] [illegible] Trans., vol. lvii.; Dr. F. Taylor, Ohio [illegible]

Digitized by Google

of resecting irreducible or gangrenous gut; to wait until we know that the shock will be the greatest possible, and the patient's powers of resistance the least possible. And we do this because we hope that the invagination may go back under simpler treatment, or because we are afraid lest we may by operating take away our patient's last chance. Our position is well summed up in the line—

"Fain would we climb but that we fear to fall."

This waiting policy, this surgery of hope, has so far been a dismal failure. Nor should we forget that in all cases that last chance is far too poor to be relied upon for permanent success, and that in infants it practically does not exist.

To attempt to draw any comparison between the numbers of successful and unsuccessful cases would be manifestly unfair. I have included in the second list no less than nine cases (Nos. 2, 3, 4, 6, 11, 15, 17, 19, 27) in which the operation was abandoned for a variety of reasons, or in which an artificial anus was established and an irreducible or gangrenous invagination left inside the abdomen, or in which reduction was not completed. In five others (Nos. 13, 14, 25, 26, 29) removal of the whole or a part of the invagination was performed, and it is worthy of note that in not a single instance did success follow this proceeding. I do not wish it to be inferred that this serious measure is one that should on no account be undertaken. When the occasion for it arises, the choice must lie between leaving an irreducible and probably gangrenous mass *in situ* and establishing an artificial anus above it on the one hand, or making a clean sweep of the offending parts on the other. In the former case all hope is practically abandoned, and the patient is left to die unless he proves so miraculously fortunate as to survive the shock, to part with the gangrenous mass, and pass safely through dangers attendant upon its

TABLE II.—*List of Cases of Intussusception in which Abdominal Section was performed unsuccessfully.*

17	Hulke (Clin. Trans., 1879)	F., 16 years	5 days' acute symptoms	36 hours	Exhaustion; peritonitis	Tumour irreducible; artificial anus made above it; peritonitis at operation; condition of patient bad.
18	Godlee (Clin. Trans., 1883)	M., 7 months	3 days' acute symptoms	1½ days	Purulent peritonitis, probably result of operation	—
19	Godlee (Clin. Trans., 1883)	— 14 weeks	Not known	8 hours	Exhaustion; shock	Patient much collapsed at time of operation; part of tumour not reduced, and some sloughing of cæcum had taken place.
20	Warrington Haward (Clin. Trans., 1883)	M., 17 months	5 days' acute	Several hours	Exhaustion; peritonitis	—
21	Davies-Colley (Bryant, Harveian Lectures, 1884)	M., 22 years	5 days' acute	2 days	Exhaustion; early peritonitis	—
22	Symonds, 1884 (not published)	M., 5 months	7 days' acute	9 hours	Exhaustion; shock; commencing peritonitis	Condition of patient before operation bad.
23	Symonds, 1884 (not published)	F., 6 months	10 days	Several hours	...	Patient was the subject of general tuberculosis.
24	Kendal Franks (Brit. Med. Jour., Dec. 6th, 1884)	Man	...	Few hours	...	Part of gut almost gangrenous, and peritoneum had given way in several places.
25	Mayo Robson (Brit. Med. Jour., Oct. 3rd, 1885)	F., 33 years	7 days	2½ hours	Shock	Four feet of gangrenous jejunum resected, and the ends of intestine sewn together.
26	Foxwell (Brit. Med. Jour., June 5th, 1886)	Boy	10 days	...	Exhaustion	Death occurred during the attempt to resect the intussusception, which was gangrenous; purulent peritonitis existed.
27	Jacobson (not published)	— 11 months	24 hours	24 hours	...	Operation abandoned in hope that cure might occur from sloughing; the intussusception irreducible, and too large to be resected.
28	Jacobson, 1886 (not published)	M., 5 months	3 weeks; not acute	At close of operation	...	Child much collapsed at time of operation.
29	Lawford Knaggs	M., 5½ years	4 days' acute	1½ hours	Shock	Resection of irreducible and partially gangrenous intussusception. State of patient good, but after resection completed desperate.

Digitized by Google

elimination. In the latter the probability is that the patient will die; but we are justified in hoping that he may overcome the difficulties in front of him. What might have been the result in Hauf's case, where the patient survived nine days with peritonitis, had the operation been carried to a conclusion? Here, at least, the shock might have been survived. But it is to be hoped that in the future resection will not often be required to be resorted to in these cases. It will, I believe, be rarely recovered from. If the necessity for it arises, the patient will usually be in a most serious state, and the terrible shock entailed by it will almost certainly prove more than he can stand. But if the importance of immediate operation, inflation failing, becomes generally recognised throughout both branches of our profession, the necessity for it will rarely occur. Just as we must hope to abolish shock and exhaustion as a cause of death by being beforehand with them, so must we hope to eliminate cases of abandoned operation, incomplete operation, and resection, by dealing with all cases before their natural progress compels us to entertain these measures.

It will generally be admitted that in cases of this nature, even when pursuing a more chronic course, an operation of such gravity as abdominal section should not be performed without proper consultation, whether in hospital or private practice; and it is even more desirable in acute cases, where a child in robust health one day is brought within an ace of death's door the next, from causes which are neither apparent to nor understood by its friends, and who will rarely be found to appreciate to the full the perilous condition of the patient. Now consultations are not usually sought until the surgeon in charge has already consumed some time in ineffective treatment, or has himself decided that operation is desirable, and the loss of time that in this way occurs at critical periods of this disease, especially in country practice, adds very materially to the dangers of the case. It cannot be too clearly understood that the successful treatment of intussusception will to a large degree depend upon promptitude in diagnosis and vigorous and immediate action. When once the nature of a case is ascertained, a consultation should immediately be sought, at which inflation should be first employed, and, in the event of this method failing to effect reduction, the abdomen should be opened then and there. If this were adopted as a routine practice, I am persuaded far more cases of intussusception would recover than do now, and this increased success would be contributed to both by inflation and by abdominal section. Lastly, where the diagnosis remains in doubt these are urgent cases for exploratory incision. If the diagnosis halts between intussusception and fæcal accumulation—a not unlikely possibility—it is quite as justifiable to settle the point in this way, when life seems certain to pay the penalty of a mistake, as it is to decide upon the possibility of removal of an abdominal tumour by the same means when the prospect of death is not nearly so imminent. Any operator who finds that he has opened an abdomen for a lump composed of fæces under the impression that it was an intussusception will undoubtedly receive a severe shock, and the fact may be rightly described as a "surgical calamity"; but he is not in such a position as the surgeon who opens the abdomen and finds that he cannot remove a tumour. The former can assist his patient by trying to break down the mass, and the information he has gained may prove of the greatest value to his patient; but the latter can only close the wound—a sadder and a wiser man.

Huddersfield.

A SIMPLE CASE OF PLEURISY: THE INTERPRETATION OF DISEASE.

BY H. CAMERON GILLIES, M.B.

IN the spring of 1884 I used to meet a neighbour, whom I knew well, going to his business. I noticed that he was not looking well; and in reply to my "How do you do?" he generally answered, "Well, I don't feel quite the thing, but there is nothing particularly the matter." Things went on in this way for some weeks; still *nothing particularly the matter*, yet day by day looking worse, losing colour, flesh, elasticity and force, until one morning I was sent for to see Mr. B—— urgently. I went, and found there was now, at any rate, *something particularly the matter*. He was down with some violent disease—that was apparent. It was an extensive pleurisy of one side, attended by all the usual symptoms, with marked prostration and high fever. He got exceedingly low, but was well nursed and recovered well. After a few weeks' holiday he, in his own words, "felt a new man."

This was as simple and ordinary a case of pleurisy as it could be. There was nothing in the symptoms or in the pathological conditions worthy of note. The reason why I record it is that it has been for my mind the starting-point to indulge in certain speculations that have been to myself of no little interest, and perhaps not altogether wanting in practical usefulness. I beg to submit them to the generous consideration of the profession in somewhat the same order as they occurred to me.

What was the patient suffering from? As I stood by that bedside I could not help asking myself: Is that man suffering from pleurisy? Is this pleurisy a specific thing, the roots of which have extended a month or more back into the man's life? Or is this pleurisy a mere accident in the course of the real disease that has told so plainly on the man's frame during the past month or so? Am I to take the local inflammation, the occurrence of the past few hours, to determine my course of treatment against my knowledge of his declining condition for weeks past? Am I to treat the pleurisy and to forget the man? That was the beginning of my curiosity and interest in the matter.

Some short time after that I met another neighbour. He did not feel at all well; if he did not get better he would have, as he said, "to look me up." I was quite sure from his expression, and from what I knew of his assiduous labours, that he would very soon have to "look me up." In a week or two I had a note wishing me to call to see him. I examined him carefully, but could make nothing of him. He had the usual "premonitory symptoms" of acute disease, being feverish, generally upset, and very unwell. He was an intelligent man, and I had no difficulty in explaining to him that I could not give a name to his disease till perhaps the following day. I found him then distinctly set for acute rheumatism.

Initial depression in acute disease.—From these observations I determined ever after to inquire, in all cases of acute disease, whether this initial state of depression held good, and in every case and every form of disease it has. To me it has been most interesting and instructive to hear even powerfully built persons, who may have been taken with acute pleurisy or pneumonia, nephritis, peritonitis, &c., declaring, in their own valuable phrase, "It has been working on me for a long time." Sometimes it is difficult to elicit the fact, but perseverance will in every case find that "I have gone off my food," "I have had no heart in my work lately," "I have been lazy—disposed to lie about," "I have not slept well for some time back," give the indication and the necessary proof. I shall attempt to explain this further on.

A modern writer of ability has declared that nothing is more urgently required in our day than is "the rejuvenescence of the commonplace." Let that be my apology if on this I write some things that everybody knows. There is not anywhere, as far as I know, in our modern medical literature, any positive assertion that this initial state of depression is an *essential* in acute disease; though in almost every one of our better writers we meet with prophecies and indications in this way. Mr. Simon[1] says that "weakness in the sense of readiness to die is the prime cause of local inflammation, and constitutional influence only influences inflammation according as it leads to local weakness." This is the truth; but is it the whole truth? Local "readiness to die" is by this a condition precedent and, I take it, a condition essential to inflammation; and this *may be* produced by constitutional influence. I would ask how otherwise can it be produced? for I consider that here *constitutional influence* means the effect of our environment working by and through the constitution, and not anything in the constitution *per se*. Mr. Simon has given us some of the best chapters in our literature, and it is for me a pleasure to acknowledge indebtedness to him for much that is valuable. His theory of idiopathic inflammation enunciated in the same work, and to which I shall have to refer, is admirable.

Dr. Murchison[2] states that "persons in good health (not apparently so, but strictly so) are little liable to inflammation." Even of cancer he says, "In a large proportion of cases it will be found that the first symptoms of indisposition have been preceded by protracted periods of grief or anxiety."

[1] Holmes' Surgery. [2] Diseases of the Liver.

Digitized by Google

whether or not the family taint exists." This is going pretty near the truth in a cautious, perhaps doubting way. The observation is a purely clinical generalisation, and as such from such a man it is of much value. My humble opinion is that persons in strictly good health are so little liable to inflammation that—they never have it.

Anstie[3] says: "The general body energy is low when the attack (of neuralgia) occurs." And in his own sterling honest way he elaborates the fact at considerable detail, but he does not anywhere get nearer the general truth—that the fact is as true of every other form of disease as it is of neuralgia.

Erichsen says: "Old age, anything that interferes with the quality of the blood or its supply, anything that enfeebles the heart's action, *predisposes* to inflammation. Thus operation wounds are more prone to inflame after a loss of blood and in patients weakened by fever or want of food." But this, again, is only part of the whole truth. All these conditions, *anything* that produces "weakness in the sense of readiness to die," not only predispose to, but make inflammation absolutely certain in some form or other.

Graily Hewitt,[4] in referring to cellulitis, says: "The diet should be liberal; most patients are weakly and prostrated, *and there is reason to believe that this is an initial condition, and had it not been for the general weakness the patient would not in the majority of cases be afflicted with cellulitis at all.*" The quotation is so apposite that I have italicised it. He sees in his own special sphere what others have observed in theirs. His large experience of cellulitis leads him to a truth that Simon, Murchison, Anstie, and Erichsen had arrived at by studies in other directions. It all points in one way.

But this is not a modern discovery, nor can we say that it has been arrived at by any ingenuity of our better methods. It is the outcome purely and simply of clinical experience and observation. John Hunter was clear upon quite as much. "Weakness," he writes, "is seldom or never an immediate cause of disease, but it often becomes the predisposing cause, many diseases not taking place but when weakness is an attendant, as agues, scrofula, nervous, &c." Hunter was troubled with the definition of *weakness*. He found it applied to so many various conditions that he could not have written more precisely than he has as to its place and value and meaning in disease. Disease was to him an entity, a thing distinct from its predisposition, in every instance *sui generis*. But we can readily believe that if he had Mr. Simon's neat, complete definition of *weakness* as "readiness to die," he would have greatly modified many of his expressions, and his opinions would be found quite up to our modern attainments in this respect.

Abernethy's work on the "Constitutional Origin of Local Diseases" is the high-water mark of rational medicine. His charge, that "the connexion of local disease with the state of the constitution in general is either not sufficiently understood or not duly regarded by this generation of practitioners," holds quite good even in our later and more learned day. Addison says of this work: "It has extraordinary merit and originality. The substance is that local diseases are rather symptoms of a disordered constitution than primary and independent in themselves. This is a beautiful theory, and I am not disposed to deny it a large share of truth." This is very generous criticism, yet it is not sufficient; for, not only is this theory not to be denied a large share of truth, but it must be granted wholly true over the whole ground to which Abernethy applied it. And if our present-day practice and our interpretation of the phenomena of disease are not very wrong, this theory has more of truth in it and a possibility of a wider and fuller application than even Abernethy himself probably foresaw.

John Brown, of Edinburgh, was certainly a remarkable man. Perhaps no "ideas" have been so often and so completely "exploded" as his, yet somehow they turn up from time to time. There was some life in this Brown. He was in effect banished from his native land, yet he made himself quite at home abroad *more Scottico*, and now he is showing himself to some extent after being "exploded" constantly for a century. This is how he puts the matter: "A great criterion by which general diseases may be distinguished from local ones will be found in this single circumstance—that general diseases are always, local diseases never, preceded by predisposition." And he explains: "Predisposition is a middle state between health and disease; *the powers producing it are the same as produce disease.*" That is perfect. Nothing in our modern literature approaches that fine generalisation—that health, malaise (predisposition), disease, and death are in one and the same straight line. We must be clear that he uses *predisposition* in a sense different from that of modern usage. Our present-day teaching puts predisposition among the *causes* of disease, and even our clearest thinkers put it as, at any rate, a condition precedent; but Brown says, "Predisposition to disease and the disease are the same." The initial depression is the disease, says Abernethy, and it is produced by a remoter disorder of the constitution, and the pleurisy is only a symptom of that disease. The initial depression (the predisposition) and the pleurisy are one and the same disease, says Brown, and the cause or causes producing the one produces the other also, and is antecedent to and concurrent with the disease while it exists.

Perhaps the rejuvenescence of so much that may appear commonplace required an apology; but it is necessary for my purpose of endeavouring to show that disease itself, at any rate in its acute idiopathic forms, is a manifestation of the determined laws of the conservation of physical energy. This I will attempt in my next paper on *the Meaning of Initial Depression in Acute Disease.*

A RARE CONDITION OF VEINS IN THE ANTERIOR VAGINAL WALL.

BY H. T. RUTHERFOORD, B.A., M.B. CANTAB., &c.

MRS. A. D——, aged sixty-five years, married forty-six years, mother of ten children, the last pregnancy occurring twenty-six years ago; has had one miscarriage thirty years since; menstruation ceased at forty-five years of age. The patient presented a pale, sallow, rather cachectic appearance, reminding one somewhat of the cachexia seen in patients suffering from malignant disease, but she stated that she was perfectly well and of good colour until a few days before seeing me. Her history was that she had never suffered a day's illness until January 10th, 1887, when she met with an accident during the frosty weather prevailing at that time. As she was stepping off the pavement to cross the road she slipped and fell heavily on the pavement. She was helped up, and on starting to cross the road felt something trickling down her thighs, like water or blood. She returned home at once, and found she was flooding severely. As this was the first appearance of blood from the vagina for twenty years she was considerably frightened. The flooding continued for four days, becoming profuse on coughing or attempting to walk about her room; but she had to do a certain amount of work each day, as she was alone in the house and had no friends to help her. On Jan. 14th the hæmorrhage ceased, but began again on the following day, and continued off and on till Feb. 1st, when she came to see me. Physical examination showed there was a slight varicose condition of the labia majora; the vagina was small, the entrance having atrophied somewhat. Just beyond the ostium vaginæ the examining finger came upon a soft oval tumour projecting into the vagina. The cervix was small and atrophied. A small-sized Ferguson's speculum was passed, to ascertain if the hæmorrhage came from the uterus, but no blood was seen escaping from the os uteri externum, which was quite healthy. On gently withdrawing the speculum, the hæmorrhage was observed to come from a valve-like opening in the right and anterior part of the tumour, which was the size of a large walnut, having at its anterior extremity a beak-like projection. The apex of this projection was about a quarter of an inch behind the urethral orifice. The tumour was of a dark-bluish colour, its surface irregular and divided by many shallow sulci, and on touch felt like a varicocele. It was, in fact, a mass of dilated veins, projecting posteriorly into the vagina and anteriorly into the urethra, narrowing the lumen of that passage at one point in a slight degree. The treatment consisted of applying the strong solution of perchloride of iron externally over the valve-like opening, and applying pressure to the whole tumour by means of pledgets of cotton wool. A strong saline purge was ordered, and absolute rest in bed enjoined. The patient at the same time was instructed how to apply pledgets of cotton wool over the tumour, the pledgets to be ap-

Digitized by Google

plied every day. She returned in a week, said she had followed out my instructions as to rest and the daily application of pledgets, with the result that for the last one or two days she had been going about the house without being troubled with hæmorrhage. She had gained flesh and colour, and was in every way stronger. The tumour, though present, was certainly diminished. She has been seen by me once or twice since, and says she feels quite well, has had no more hæmorrhage, is doing her every day work, and does not intend to see a doctor again unless a fresh hæmorrhage attacks her.

Remarks.—Varicose and enlarged veins in the region of the vulva and in the vagina are of common enough occurrence during pregnancy, and at times give rise to serious hæmorrhages during or after parturition; but I have never seen, nor can I find recorded in any volume of obstetrics or gynæcology with which I am acquainted a similar condition of dilated veins in a subject sixty-five years of age, who was, as far as one could judge from examination, perfectly healthy, and who certainly presented no other signs of varicose veins in any other part of the body. No tumour was found in the pelvis, either per vaginam, per rectum, or on abdominal palpation, which might have accounted for this varicosity, and I must confess I am at a loss to explain its occurrence. The rupture and consequent hæmorrhage are easily accounted for by the extra pressure in the venous system, acting on what was evidently a weak part in the wall of the dilated vein. The sudden hæmorrhage with the almost cancerous cachexia presented by a patient of her age, the mother of ten children, might easily have led one to suspect malignant disease of the generative organs.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A PROPOSED MODIFICATION OF MOORE'S TREATMENT OF ANEURYSM.

BY W. E. STEAVENSON, M.D. CANTAB., M.R.C.P.,
ELECTRICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

THE papers read before the Royal Medical and Chirurgical Society on April 12th on the Treatment of Internal Aneurysms by the Introduction of Steel-wire into the Sac, and the subsequent discussion thereon reported in THE LANCET of April 16th, have suggested the following modifications and additions to the operation:—That the wire used should be soft iron wire, instead of steel, of No. 29 gauge according to the Birmingham scale. That the introduction should be accomplished by means of a perforated needle fitted to a handle similar to that used for the operation of staphyloraphy, as suggested by Mr. T. Smith. That the wire should not, as in the latter instance, be previously wound upon a reel or bobbin, but should be paid out from a tolerably large coil or skein so as to reduce the chance of kinking. The amount of wire to be used will vary in accordance with the size of the aneurysm. That the perforated needle should be a straight one made of ivory, and much longer than those ordinarily employed for cleft palate.[1] That the needle should be introduced to such a depth that the point would be well within the aneurysm. When sufficient wire has been introduced, it should be cut off near the hank or coil from which it was paid out; the handle detached from the needle; the needle left in the aneurysm with the end of the wire protruding from it. That the wire should then be connected with the *positive* pole of a strong galvanic battery; a sponge, or tin and amadou plate electrode, moistened in salt-and-water, should be attached to the negative pole and placed on some indifferent part of the body. That the circuit should be closed, and a current of from fifteen to twenty milliampères passed through the aneurysm until it became consolidated, or for thirty minutes. The pad connected with the negative pole should be moved to different parts of the body when found necessary, so as to avoid any particular spot becoming blistered or sore. That at the conclusion of the operation the remaining piece of iron wire protruding from the needle should, if not already detached by the decomposition which had taken place in the sac, be pushed through the perforated needle by a blunt trocar into the aneurysm, and the small puncture hole closed by a piece of strapping. The introduction of soft iron wire into the sac of an aneurysm would be a great additional advantage in the employment of electricity over the usual method of galvano-puncture. When attached to the positive pole of a battery, coagulation would be encouraged within the aneurysm, and the wire itself would undergo decomposition with the formation of chloride and oxide of iron, which would, in addition, exercise their own specific coagulating properties.

It was mentioned by Dr. Pringle in the discussion already alluded to that the clot resulting from electrolysis is distinctly softer than an ordinary clot. If this be so, it is no doubt partly due to its rapid formation, and it would no doubt shrink and consolidate, and possibly become as firm as any other clot when of a similar age. In the operation now suggested, the clot produced by electrolysis would have a long and extensive origin, and be entangled in innumerable positions by the coils of the iron wire. Another probable reason why the coagulum formed by electrolysis "appears very frequently not to be stable, but to be liable to melt down again into the blood stream,"[2] is because needles attached to both poles, or to the negative pole, have been used. Around the negative pole the blood is coagulated into a yellow friable alkaline mass, composed to a great extent of gas bubbles, which very quickly breaks down. Around the positive pole the clot is smaller, firmer, and darker in colour, and has an acid reaction. From the physical laws of electrolysis, and from the experience already obtained, it would seem probable that a combination of Moore's treatment of aneurysm with that by galvano-puncture, as here sketched out, would offer a very fair chance of a successful result.

ASPIRATION OF THE URINARY BLADDER.

BY A. WILKINSON, M.D.

HAVING seen Mr. G. Buckston Browne's letter in your issue of Feb. 26th, also the report of and discussion on a paper read by Mr. W. H. Bennett at a recent meeting of the Medical and Chirurgical Society on a case of rupture of the urinary bladder which terminated fatally as a direct result of aspiration above the pubes, I am induced to send you the notes of a case in which the bladder was aspirated by this method sixty-nine times in immediate succession by myself and assistant alternately.

The patient, a large fat man, aged sixty-seven, had been an invalid three years owing to brain mischief, and during that time was gradually getting worse. His intellect was so far impaired that none of his statements could be credited, but, as far as could be ascertained, he had had some difficulty in micturition, but no actual retention till Sept. 3rd, 1885, the date of my first visit. The history, condition, and symptoms—aphasia and paresis—pointed to cerebro-spinal disease; but an enlarged prostate, fully the size of a tennis-ball, undergoing some active change, probably inflammatory, was the immediate cause of the retention. The bladder was greatly distended, and the urethral passage narrow, tortuous, and painful. With considerable difficulty a No. 5 gum-elastic catheter was passed, and about thirty ounces of urine drawn off. This was repeated on the 4th and again on the 5th, but from the latter date to Oct. 16th, as no catheter could be passed, supra-pubic aspiration was resorted to, sometimes once a day, more often twice. The punctures were made with a fine needle corresponding in size to No. 19 wire. The natural route to the bladder was still occluded, and aspiration having been performed fifty-four times, on Oct. 16th I punctured above the pubes with Pearce's trocar and cannula with the view to establish a permanent outlet. The cannula was tied in, but owing to the patient's interference, he twice pulling it out, that course was abandoned. The aspirator was again brought into use, and continued until the 25th, when I succeeded in passing a No. 3 soft catheter, to which an exhaustor was attached, and the

[2] See Mr. Timothy Holmes' Lectures on the Surgical Treatment of Aneurysm. (THE LANCET, Sept. 7th, 1872, p. 336).

Digitized by Google

urine drawn off. The catheter was tied in, but removed by the patient in his demented condition. On the morning of the 27th about a teaspoonful of pus suddenly gushed from the urethra, and on passing the catheter about four ounces came through it, fairly conclusive that prostatic abscess had been the cause of the retention. Catheters gradually increasing in size were passed from day to day, until No. 10 could be easily introduced even by the patient's attendant. In this case the urinary bladder was aspirated above the pubes sixty-nine times in succession. All the punctures were made within an area about the size of a crown-piece, the most recent being as far removed as possible from the previous one. Small subcutaneous shot-like indurations followed the punctures, but soon disappeared, leaving no ill effects. The urine, which at no time contained sugar, after three or four aspirations became excessively large in quantity, being secreted at the rate of five ounces an hour, often more, and subsided to its normal amount when the aspirations were discontinued. The patient residing at a distance of nearly four miles, and the urine being so large in quantity, over-distension was not an unfrequent occurrence, but notwithstanding this unfavourable circumstance the bladder maintained its own fairly well throughout, the urine only becoming slightly turbid toward the last. The patient so far recovered that his attendant was enabled to relieve him by a soft catheter when necessary.

Shaftesbury, Dorset.

A REMARKABLE CASE OF FIBROMA MOLLUSCUM.

By FRANCIS W. CLARK, L.R.C.P., M.R.C.S.

THE following notes of a case of fibroma molluscum will, I think, be of interest from the exceptional rarity of certain of the features presented by it.

The patient, a man aged seventy, is covered from head to foot with a number of subcutaneous tumours of various sizes, some of them being pedunculated, while others are sessile. These tumours are of very soft consistence, and there is an entire absence of that lobulation which is so characteristic of subcutaneous fatty tumours. The largest of these tumours is one which forms a complete anklet around the left ankle. One of the smaller pedunculated growths was removed for further examination, and on section it was found to consist of a gelatinous translucent material, which under the microscope was seen to be composed of a very fine reticulum of fibrous tissue, containing in its meshes a transparent gelatinous material—myxo-fibroma. The patient dates the onset of this condition from a fright he received thirty years ago, when he happened to be a spectator of a severe railway accident. He states that since that time these tumours have gradually appeared, most of them developing during the first twelve months subsequently to the fright. It is a curious feature in the case that the patient's daughter, who was born some twelve months after the appearance of the tumours, is also covered with similar growths, though they are less numerous. The case was shown for me by my friend, Dr. J. Kingston Fowler, at the Clinical Society of London in February last, and was then considered to be unique.

Croydon Infirmary.

DISLOCATION FORWARDS OF THE HAND.

By CHARLES AITKEN, M.B.

THE following report of a dislocation of rare occurrence may be of interest:—

In July last W——, a boy aged sixteen, was brought to my surgery with the history that he was sent up a tree to fasten a rope to one of its branches, so that it could be pulled down in a certain direction. While the boy was among the branches his master cut away at the stem, and the boy fell. He was not sensible for a few minutes after falling, and on becoming conscious thought that his arm was broken. Neither did he remember whether he fell with the palmar or dorsal aspect of his hand facing the ground. On examining him, I found that he had a dislocation forwards of the right hand on the arm and almost compound on the palmar aspect. The ends of the radius and ulna could be felt distinctly on the back, and there was a rounded swelling on the front. On pulling the hand away from the arm the dislocation was reduced with a loud snap. There was some swelling for three months over the carpal bones in front, but that has entirely disappeared and the boy's arm is now as well as usual. On referring to the surgical dictionary by Heath, and to Holmes' and Hulke's Surgery, I see it is mentioned that the above dislocation is a very rare one indeed.

St. Mawes, Cornwall.

ABSENCE OF THE OCCIPITAL BONE AND SKIN IN A NEWLY-BORN INFANT.

By WILLIAM FRASER, M.B. T.C.D.

I RECENTLY came across a curiosity which will no doubt be of some interest. Among the books at my command (including Dr. Neale's "Digest," Sydenham Society, 1877), I cannot find any mention of a similar case.

About 3 A.M. on Nov. 20th I was asked to go to Mrs. W——, living about eight miles away, who was in labour with her third child. On my arrival there was a mysterious silence and glances which betokened that the baby was stillborn, but the afterbirth was retained. Having seen to the mother, I turned to the child, and the mystery was then explained. I found a female infant of about seven months and a half (though the mother says she did not expect to be confined until the end of December). The body was fairly nourished and well formed, the head flattened in its antero-posterior diameter, the eyes large and protruding; a black mass on the back of the skull proved to be the cerebellum exposed to view, with complete absence of the occipital bone and the skin covering it. On loosening the cerebellum and lifting it up I could see the base of the skull, and was able to push a piece of wood down the spinal canal. No cause could be assigned by way of fright or anything else.

MIDDLESEX HOSPITAL.

CASES OF SARCOMA IN CONNEXION WITH KNEE, FOOT, AND EAR; RESULT.

(Under the care of Mr. HULKE.)

THE cases of sarcoma reported in our impression of May 28th (p. 1086) illustrated the occurrence of this form of new growth in young adult life, evincing in its progress clinical features as malignant as those exhibited by any carcinoma. The first case of the present series exemplifies the same facts; it illustrates local recurrence after excision, and infection of remotely situated viscera manifesting itself at a date long after amputation of the limb. But this case has an additional interest in the illusory resemblance presented by the primary tumour in its clinical characters, in its apparent seat and connexions, and in its naked-eye appearances after removal to a multilocular ganglion. The deception was occasioned by the presence of the myxomatous elements, which simulated the structureless colloid contents of a common ganglion. The second case illustrates the occurrence of melanotic sarcoma in middle life in a form which, as regards the primary tumour, deceptively resembled epithelioma, and which led to its being mistaken for this—a mistake not unlikely to occur where the melanotic constituent exists in a minimum quantity in the original tumour, and only attains considerable development in the larger secondary masses, a by no means uncommon circumstance. The frequent development of melanosis in moles is too well known to need more than passing mention. The sole and the clefts between the toes would seem to be the favourite situations for this form of sarcoma, possibly because in these situations any little, apparently trivial, tegumental disorder is more exposed to pressures and to other kinds of local irritation. The third case is an instance of melanotic sarcoma occurring at an unusually early age, and in a very

Digitized by Google

unusual situation. Here also the tendency to rapid local recurrence was very strongly pronounced. It is to be regretted that the entire auricle was not in the first instance excised, but the mutilation thus involved was regarded by the patient as so likely to prevent his continuing to obtain employment in his calling that he was averse from entertaining the recommendation to submit to it.

CASE 4. *Myxo-sarcoma; primary tumour simulating multilocular ganglion; recurrence in liver after excision; amputation; death from recurrence in lungs about four years and a half after the first operation.*—A milliner, aged eighteen, a blonde, apparently in the enjoyment of excellent health, was admitted into Regent ward on Jan. 13th, 1880, for a swelling of the left knee joint, latterly accompanied with so much pain as to render walking very difficult. The swelling was about the size of a pigeon's egg; it was firm, yet somewhat elastic; its consistence suggested that it might be a very tightly distended cyst. When the leg was extended, the swelling seemed fixed to the femur just above and slightly behind the external condyle; but when the leg was flexed a distinct mobility of the swelling upon the femur was recognisable. It was in close relation to the tendon of the biceps muscle, which passed behind and internal to it. The patient stated that about four years previously she first began to suffer pain in the knee, which was regarded as rheumatic; the pain gradually increased, and this latterly to such an extent that the limb was nearly disabled. The swelling was first noticed about one year before she entered the hospital. The diagnosis was a ganglion connected with the bicipital sheath, tightly distended. A few days later the swelling was exposed and dissected out. Its rough characters were those of multilocular cyst, the spaces of which were filled by a jelly-like substance. The wound healed well, and the patient went home on Feb. 26th.

On Aug. 25th, 1881, being about nineteen months after the first operation, the patient again sought admission into the hospital. A note of her condition at this time states that there was at the outer and posterior aspect of the knee a subglobular nodular swelling, three inches in diameter, crossed by the scar of the former operation. Its consistence was not uniform, being mostly firm, but in some situations so soft and elastic as to occasion the idea of fluctuation. The mass was plainly now attached to the femur. The patient was unable to fix the date of the reappearance of the tumour, but she thought that it was not very long after she left the hospital. She attached so little importance to it that it did not deter her from marrying. Amputation was proposed by Mr. A. Clark, then in charge of Mr. Hulke's ward, but it was declined by the patient, who left the hospital.

On Nov. 4th following the patient returned, looking thin, anxious, and worn. The tumour had in the interim considerably increased. The limb was removed by a circular amputation at the middle of the thigh. The femoral artery was secured by torsion. The stump suppurated and healed slowly, so that she did not leave her bed until Jan. 4th, 1882. At the middle of the month she was allowed to return home, having gained flesh, and feeling stronger and looking much better than before the amputation. The tumour proved to be a myxo-sarcoma, springing apparently from the periosteum of the outer condyle of the femur. The preparation is preserved in the Middlesex Hospital museum, No. 544, catalogue.

The patient was not seen again until the autumn of 1885, when she entered a medical ward for intense dyspnœa, under the care of Dr. Cayley, who referred it to sarcomatous infiltration of lung.

Death occurred suddenly. At the necropsy, Dr. Fowler found the upper lobe of right lung compressed by a sarcomatous mass, a portion of which intruded into the right bronchus. From this a detached nodule of the size of a walnut had escaped into the trachea and caused suffocation. The middle lobe of the right and the lower lobe of the left lung each contained a small knob of tumour. Its histology was that of spindle-cell sarcoma.

CASE 5. *Melanotic sarcoma; primary tumour in the sole of the foot, simulating epithelioma; recurrence after excision, and wide dissemination of secondary tumours.*—E. W——, aged fifty-four, an extremely fat woman, was admitted into the Regent ward on June 26th, 1880. In the middle of the sole of her right foot was an ulcer of the size of a shilling. Its edges were abrupt, raised, and slightly everted, and its base was warty. It was tender and painful, and prevented her walking. She stated that the sore had begun about one year previously in a small mole which she picked because it itched. The circular outline of the ulcer was not unlike that of a perforating ulcer, but its situation was in the hollow of the sole, and not in a part subjected to pressure, as the balls of the toes or heel, situations for which perforating ulcer would appear to exercise a selection. The edges of the ulcer were everted and not undercut, and the base was warty, both of which circumstances were unfavourable to the supposition of its being a perforating ulcer. The absence of all symptoms of tabes dorsalis, with which malady perforating ulcer so frequently concurs, was also against this view of its nature. The probabilities were considered to be in favour of its being an epithelioma. On June 30th it was very freely excised. Cicatrisation proceeded very slowly. This was attributed firstly to the little extensibility of the tegument in the sole. On July 27th, the wound having almost closed, and appearing healthy, she was allowed to return home. A few weeks later, when she next presented herself at the hospital, there was evidently a renewal of the growth at the seat of the operation, and now, first, enlargement of the inguinal and also of the lymph glands along the course of the external iliac vessels was detected. This extensive glandular implication barred further operative measures. She was seen at intervals in the course of 1881–84; in the latter year she died. Large tumour masses appeared in the leg and thigh, upon the right shoulder, and in the neck. They were bossy and elevated, and imparted to the attenuated skin covering them the bluish-black appearance characteristic of melanosis.

CASE 6. *Melanotic sarcoma of auricle; excision; recurrence; second operation; recurrence.* — A footman, aged twenty-three years, was admitted into the hospital on March 2nd, 1883. In the lobe of the left auricle and on the posterior border of the helix, at its lower end, he had two small rounded swellings of a violet-bluish colour, overrun with dilated capillary bloodvessels. The upper of the two swellings was of the size of a small grape; the lower was slightly larger. They were not tender or painful. No enlargement of the cervical lymph glands or other swellings were discoverable. He said that the upper swelling had been first observed about five years previously, being then as large as a "pea." He had noticed the existence of the lower swelling about one year. The appearance of the upper swelling was slightly suggestive of hæmatoma, but this is commonly an incident in perichondritis of traumatic origin, being of not very infrequent occurrence in pugilists. Here, however, there were not any circumstances pointing to injuries of the external ear, and there was an absence of tenderness and of heat; besides, hæmatomata are limited to the cartilaginous part of the auricle, and here the lower swelling was seated on the lobe. The diagnosis of hæmatoma was also rebutted by the duration for five years from the first appearance of the upper swelling. The appearance of the swellings was very suggestive of melanotic sarcoma, but the duration threw doubt on this supposition, and the infrequency of such new growths in the auricle, and the patient's age, tended to confirm this doubt. He would not permit more than the least possible mutilation of the ear consistent with the removal of the swellings. These were therefore excised. Their naked-eye appearances and histology were those of melanotic sarcoma. On March 10th he returned home with the wound apparently soundly healed. In the following August he returned with a recurrence of the melanosis in the scar and in the neck. Mr. Lyell, then in charge of Mr. Hulke's wards, freely excised the masses in the ear and neck. The wounds healed, but before long such extensive recurrence occurred in the neck as placed the patient beyond further surgical aid.

HERTFORD GENERAL INFIRMARY.

A CASE OF HYPERTROPHY OF THE SPLEEN; DEATH; NECROPSY.

(From notes by Mr. H. G. SHORE, House-Surgeon.)

E. T——, aged twenty-eight, married, came to the out-patient room on April 4th, having walked two miles and a half. She was evidently suffering great pain, and was considerably exhausted, so she was sent into the ward at once, when her temperature was found to be 102·8°. The patient has had five children, the youngest two years and three months old. Catamenia normal. She says she has had a tumour in the abdomen since last August, but her friends say she has been looking ill for two years. She has suffered

Digitized by Google

pain during the last fortnight, but has not consulted any doctor. She says the tumour was first noticed just above the left anterior superior spine of the ilium, and has been getting larger for the last four or five months. There was no history of malignant disease, of syphilis, or ague (?). Urine: sp. gr. 1020; acid; no albumen.

On examination, a tumour was found occupying the whole of the left side of the abdomen, with a well-defined inner and lower edge, it being just possible to get one's fingers between the lower margin and the ilium. Percussion did not give an absolutely dull note. The tumour felt hard, and extended right back into the lumbar region. The patient was in considerable pain, which was, however, relieved by hot fomentations with laudanum sprinkled thereon.

April 5th.—The patient slept about six hours after the hypodermic injection of morphia (gr. $\frac{1}{4}$), and atropine (gr. $\frac{1}{100}$). Temperature 104·2°. Systolic murmur audible at the base of the heart. Nothing remarkable about the lungs, excepting loud breathing over the right back. Uterus normal.

6th.—Temperature 103°. The pain still continues, but is relieved by laudanum fomentations and by an anodyne mixture containing fifteen minims of tincture of opium. Urine: sp. gr. 1020, albuminous, and contained pus and blood. Fæces dysenteric in character, and apparently contained pus. Farinaceous diet ordered, with beef-tea, soda-water, and brandy (two ounces). There was some difficulty in obtaining the urine, and possibly the specimen was not pure.

8th.—The patient seemed somewhat better yesterday, was in less pain, and the temperature 102°; but this morning she is in great pain, temperature 103·8°, lips purple, and apparently some interference with circulation. An exploratory puncture was made, and two ounces of sanious serum drawn off by means of the aspirator.

9th.—In less pain; tongue not so furred; temperature 102°; pulse 120, soft, of fair volume.

10th.—Tongue dry; sordes about teeth; very exhausted; pulse 124, not feeble. Exhaustion shows itself principally in shallow respiration, &c. Veins of right iliac region very distinctly visible. Less peritoneal distension. Wound of puncture healed; tumour unaltered in appearance. Noon: The patient became cyanosed. A subcutaneous injection of ether (twenty minims), to be repeated in an hour, was administered. Took nourishment well, but died at 5 P.M.

Necropsy.—Thoracic viscera perfectly normal, with the exception of rather an excess of fluid in the pericardium. On opening the abdominal cavity, an enormous spleen was found filling up the whole of the left side from the diaphragm to the iliac region; it appeared perfectly normal, except that the capsule at the posterior border, about the centre, showed signs of inflammation; on section, the organ was quite natural in appearance. Weight of spleen 5½ lb. The liver was greatly enlarged and fatty; kidneys normal, but left ureter distended; bladder and uterus normal. There was evidence of enteritis, but to no very marked extent.

The enormous size of the spleen is so remarkable as to justify the case being published. Unfortunately, the acute pain and high temperature prevented any large operative measures being attempted.

STAMFORD, RUTLAND, AND GENERAL INFIRMARY.

CALCULUS VESICÆ; SUPRAPUBIC OPERATION; DEATH; NECROPSY.

(Under the care of Mr. GREENWOOD.)

N. R——, male, aged four years and a half, a well-nourished, healthy-looking child, was admitted with the following history. The symptoms of calculus had been noticed for six months, and had been worse for the last two months. No blood had been seen in the urine and no albumen was found, but considerable phosphatic and mucous deposit. There was no phimosis, but the prepuce was adherent to the glans to some extent. On sounding, the instrument struck and passed over a calculus lying to the right side, and the impression was that it was a large one.

On Oct. 18th, 1886, under the influence of ether and chloroform, an elastic bag was passed into the rectum and partially distended; but the bag seemed rather too large for this case. A gum-elastic catheter was passed, and three ounces of boracic acid lotion injected into the bladder. The catheter was withdrawn, and an elastic cord tied around the root of the penis. The rectal and vesical distension were not sufficient to throw the outline of the bladder into prominence. The abdomen was opened in the mid-line by an incision two inches long upwards from the symphysis pubis. It was not easy to feel the bladder at first, as it eluded the finger, falling over to the right side. Two silk sutures were passed through the bladder wall, and between these the bladder was opened. The stone was then felt lying transversely in the bladder, which was contracted on it, the fluid contents having escaped. The position of the stone was changed with the nail of the forefinger, and then it was extracted with fine lithotomy forceps. The stone, which was flattened and oval in shape, weighed 3 drs. 6 grs. A drainage tube the size of a No. 8 catheter, with two side openings at the lower end only, was introduced for two inches and fixed in place to the abdominal wall by two horse-hair sutures; it extended for six inches outside the abdominal wound. No sutures were placed in the bladder. Deep catgut sutures and superficial silver ones were used for the upper part of the wound. The dressing was iodoform and Gamgee's cotton-wool tissue, through which the drainage tube passed. The child was placed on his left side in bed, and urine began to drain through the tube in half an hour without a stain of blood. The dressings were renewed every morning, and urine continued to drain off through the tube until the fourth day, when it was removed, and two hours afterwards half an ounce of urine was passed per urethram.

Oct. 31st (thirteenth day).—Has been kept on milk diet, and at no time has there been any rise of temperature. About half the urine passed per urethram (an ounce at a time), the rest per abdominal wound, which is granulating from the bottom and looking well.

Nov. 4th (seventeenth day).—Yesterday evening he was sick after taking some milk, but no rise of temperature was noticed, and no change in the local conditions, but at 7 A.M. to-day he became collapsed and died in twenty minutes.

At the post-mortem examination the bladder wound was united, except at one point admitting a fine silver probe. Bladder contracted, with half an ounce of urine in it, and with hypertrophied walls. No escape from the wound into the abdomen could be detected, and the kidneys were healthy.

What was the cause of death? The child was quite well up to the attack of sickness.

Medical Societies.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Wednesday, June 1st, Dr. John Williams, President, in the chair.

It was unanimously agreed that an address should be presented from the Society to Her Majesty the Queen on the occasion of the completion of the fiftieth year of her reign.

Microscopic Sections of a Human Embryo.—Mr. LOCKWOOD exhibited a series of sections showing absence of spinal medulla with arrest of the development of the spinal column and retroflexion of the lower limbs. The embryo was eight millimetres long, and had reached about the sixth week of intra-uterine life.

Fœtal Membranes were shown by Dr. BLUETT in which two tumours were found. The labour had been natural and delivery took place at full term.

Spontaneous Gangrene of Cervix Uteri and Base of Bladder.—The parts were shown by Dr. HERMAN, who said they had sloughed away spontaneously from a woman who had not been pregnant for eight years.

Hydatids from the Mesentery were exhibited by Dr. Malins; a Fibroid of the Ovary by Dr. John Williams; a Fibro-cyst and a Solid Fibroma of the Ovary by Mr. Meredith; and a Fibroma of doubtful origin by Mr. Malcolm. These four tumours and Dr. Bluett's specimen were referred to a committee.—A Sloughing Fibroid Polypus was shown by Dr. W. Duncan.

Cæsarean Section.—Dr. C. J. CULLINGWORTH gave an account of this case. A rachitic dwarf, aged thirty, 4 ft. 2 in. in height, was sent at full time to the author. The pelvis was generally contracted and flat, the estimated conjugata vera being two inches and a quarter. The child was alive. There was great albuminuria, with œdema of the abdominal

Digitized by Google

wall, labia, and legs. Labour began spontaneously, and when the os uteri was as large as a florin Cæsarean section was performed with full antiseptic precautions. The child weighed 5 lb. 9 oz., and was extracted by one leg; it was partially asphyxiated but soon recovered. After clearing the uterus of the placenta and membranes, its lower segment was constricted by an elastic ligature. The loss of blood was trifling. The uterine wall was united by four deep silk sutures, and the peritoneal edges by six finer superficial silk sutures. The patient died twenty-nine hours after operation, the temperature remaining under 100° F. until two or three hours before death, when it rose to 100·8° F., pulse 140. At the post-mortem there was no sufficient cause of death found except acute parenchymatous nephritis.—The PRESIDENT wished to know if the kidneys and urine had been examined microscopically, and the quantity of urine passed after delivery. The low temperature was characteristic of uræmia, and he thought there was fear of carbolic poisoning where the kidneys were badly diseased.—Dr. HORROCKS thought death was probably due to shock, and that the elastic ligature compressing the plexuses of nerves as they enter the uterus would increase this.—Dr. J. PHILLIPS asked by what sign the seat of the placenta was determined, and why the uterus had been brought outside the abdomen before extracting the child?—Dr. W. DUNCAN considered that it was better to place the elastic ligature around the cervix before opening the uterus.—Dr. LEWERS thought that, although improved results in Cæsarean section had been reported from abroad, such success had not been met with in this country, and he preferred the old rule of delivery, when possible, *per vias naturales*. In the case under discussion this was possible.—Mr. MEREDITH though that the Porro operation might have been preferred with a view to ensuring against the possibility of a future pregnancy.—Dr. MATTHEWS DUNCAN said that neither he nor perhaps anyone in this country had large experience of Cæsarean section, and that it was to Germany that we must look for the guidance of experience and such wonderful success as that of Säuger, Leopold, Credé, and Gusserow. It was such success alone that should and would lead us in the great practical question, and their cases showed at present a less mortality with Cæsarean section than with Porro's operation. Both operations had a place in obstetric surgery, and he thought Dr. Cullingworth had rightly selected Cæsarean section; while in the case to which Mr. Meredith had alluded, as there were several large fibroids, Sir Spencer Wells had wisely selected Porro's operation. No amount of eloquence about the abolition of craniotomy would help forward that much-to-be-desired result. There had been much of such talk. Nothing but success in some alternative operation would do the least good.—Dr. MATTHEWS DUNCAN approved of the course adopted by Dr. Cullingworth, and thought the renal disease was probably the chief cause of death.—Dr. CHAMPNEYS said that the seat of the placenta could not be diagnosed by uterine souffle, and that often there was no sound at the seat of implantation, while it could be heard after the removal of the placenta, and in cases where there was no placenta, as in fibroid tumours. It could not be too strongly urged that the uterine souffle was no guide whatever to the placental site. He thought the tracing was typical of a generally contracted flat pelvis, and that, although four or five years ago Cæsarean section would not have been justified, improved methods and antiseptics rendered it the proper practice as an operation of election.—Dr. CULLINGWORTH replied.

On the Mechanism of the Third Stage of Labour: the Separation and Expulsion of the Membranes.—Dr. F. H. CHAMPNEYS reviewed the literature of the subject, and the various views expressed. These amount to four: (1) the peeling off of the membranes by the traction of the descending placenta; (2) separation by effusion of blood; (3) wrinkling of the membranes by uterine contraction and retraction; (4) separation of the lower pole of the ovum by retraction of the lower uterine segment. The author dismissed No. 2 on the ground that the quantity of blood lost in an ordinary labour is too small to produce this result, and that, with the usual excentric implantation of the placenta, this mechanism would fail of its purpose. He criticised the expression "weight of the placenta," as having influence on the mechanism in the recumbent attitude, and also the expression "leaving (the process) to nature," as applied to its course in the recumbent attitude. He explained the natural process as follows: (1) Separation of the lower pole of the ovum by retraction of the lower uterine segment during the "premonitory" stage of labour. This requires a complete "bag of waters." (2) Wrinkling and partial separation of the membranes by diminution of the internal surface of the uterus. This requires some escape of the waters. (3) Peeling off of the membranes by the traction of the descending placenta. This requires the evacuation of the uterus. The rupture of the membranes at the proper time is an integral part of the normal process. The first stage in the process seems calculated to prevent a very common defect—viz., the adhesion of the membranes round the lower uterine segment.

Tubo-ovarian Cysts.—Dr. W. S. A. GRIFFITH, in a paper on this subject, referred to the scanty literature of the subject, and gave an abstract of all recorded cases obtained, numbering nineteen. The literature of the subject is comprised in the original papers by Adolphe Richard, and in recent ones by Olshausen and Burnier. The specimens were divided into two groups, a small group of four in which the ovarian portion of the cyst is multilocular, the tube communicating with one loculus, and a group of eighteen in which the cyst is unilocular. The question of unilocular cysts of the ovary was discussed, and these were identified with the larger unilocular cysts described by Olshausen. The subject of the formation of tubo-ovarian cysts was subdivided, and received the following answers:—That the dilatation of the tube, and the formation of the ovarian cyst, are usually secondary and not primary factors in the formation of tubo-ovarian cysts. That the application of the tube to the ovary is physiological or possibly accidental. That the permanent adhesion of the two is effected by adhesive inflammation. That the communication between the two is generally either a primary occurrence or takes place at a very early period in the formation of the cyst.

The discussion of these two papers was deferred till the next meeting.

ANATOMICAL SOCIETY.

A MEETING of the above Society was held on the 6th inst., when the following propositions of the committee were adopted:—"That not less than four meetings be held in each year. That the officers of the Society shall consist of a president, three vice-presidents, a treasurer, a council of twenty, and three secretaries. That the officers be elected by ballot at each annual meeting. That as far as possible, in the election of president and vice-presidents, there shall be two representatives of England, and one each from Scotland and Ireland. That there shall be a secretary for England, one for Scotland, and one for Ireland. That the Council shall, from amongst their number, select six members to form, together with the president, vice-presidents, treasurer, and secretaries, a committee of management."

It was announced that the next meeting would be held on July 7th, at which papers would be read by Professor MacAlister, F.R.S., Dr. Brooks, and J. Bland Sutton; and specimens &c. exhibited by R. J. Godlee, Dr. Bruce Clarke, James Berry, and Dr. W. J. Collins.

The following is a list of the officers elected:—President: George Murray Humphry, F.R.S. Vice-Presidents: J. Struthers, M.D.; John Wood, F.R.S.; and Daniel John Cunningham, M.D. Treasurer: Charles Stewart. Secretaries: C. B. Lockwood (England); David Hepburn, M.D. (Scotland); and William Thornley Stoker, M.D. (Ireland). Council: William Mitchell Banks, John Curnow, M.D., J. N. C. Davies-Colley, Edward Bellamy, Frank Beddard, John Cleland, M.D., G. B. Howes, John Langton, Henry Morris, Edmund Owen, Thomas Pickering Pick, Johnson Symington, Robert Reid, M.D., George D. Thane, Sir William Turner, F.R.S., Frederick Treves, Alexander Macalister, F.R.S., Bertram Windle, Alfred H. Young, and Arthur Thomson.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

AT the ordinary meeting held on May 6th, Dr. S. C. Smith, President, in the chair, the following papers were read:—

Diphtheritic (?) Slough of Vagina.—Dr. BLACK was called to the case of a girl suffering from feverish conditions, with slight swelling of the neck. Nothing else was complained

Digitized by Google

of but a slight itching of the genitals. Examination showed an acute gangrenous condition of the vulva, with ashy sloughs, resembling a diphtheritic inflammation. Later there were suppurating glands in the axilla covered with slough, and the gums were red and spongy. Under general medicinal treatment and the local application of iodoform recovery took place. There was no subsequent paralysis. No history of infection could be made out. The theory of diphtheria was put forward as a possible hypothesis.—Dr. CHURTON related a case where there was extensive sloughing of black colour in the soft palate of a man, causing death from hæmorrhage. No kind of infection could be discovered.—Dr. CAMERON thought the case could hardly be diphtheritic, from the character of the ulceration and the fact that diphtheria was seldom solitary.

Fracture of Thigh in a case of Paraplegia.—Dr. BLACK described a case where a man who had been paraplegic for thirty years, from an accident to his back when a boy, fractured his thigh. It was set without pain or spasm, and healing was rapid and complete.—Dr. S. C. SMITH had seen a similar case, healing with good results.—Dr. CAMERON had seen a fracture of the thigh in a case of locomotor ataxy, which was rapidly fatal.

On the convenience of estimating the amount of Urine voided by its Weight.—Dr. SPOTTISWOODE CAMERON spoke of the difficulty in private practice of obtaining exact measurements of urine passed, owing to the absence in most houses of measures less than half a pint. Weights, however, down to half an ounce, were always at hand, and it was easier for a patient to weigh the urine than to measure it. To simplify the calculation required, the following method was accurate enough for ordinary amounts of urine: write down the weight of the urine in ounces and decimals; multiply this number by the last two figures of the specific gravity, placing the product beneath and three places to the right; the difference is the bulk of the urine in fluid ounces.—Dr. S. C. SMITH said people had an objection to using ordinary measures for urine, and this plan was free from objection.—Dr. GRIFFITHS spoke of the necessity in estimating the urine passed of beginning with an empty bladder, the first morning's urine being disregarded, and measurement being begun from that time; this was the plan now adopted in the infirmary.

Emmet's Operation.—Dr. BRAITHWAITE described fourteen cases in which this operation had been performed. As operations, eleven were successful, two imperfect, and one a failure; but as relieving the symptoms complained of by the patients, six were successful, four unsuccessful, and two were complicated with other affections, which rendered the result difficult to estimate. The lacerations generally occurred in multiparæ, and the symptoms varied according to the amount of cicatricial tissue in the angle of the wound.

Therapeutic Memoranda: Ergotine; Hydriodate of Hyoscine.—Dr. ALLAN spoke highly of ergotine in the treatment of cough, whether phthisical or bronchitic. Given in a nightly draught in doses of form ten to twenty grains, it was safe, and seemed to greatly relieve cough and promote expectoration, without any disadvantages. In children he gave from four to six grains. He had tried also sclerotic acid in doses of from one to two grains. He recommended also hydriodate of hyoscine as a cerebral sedative where morphia or chloral was unsuitable, giving one-hundredth of a grain subcutaneously as an average dose. He had found it very useful in delirium tremens.—Mr. OAKLEY preferred the hypodermic use of ergotine, and samples varied greatly. He never used a sample for this condition until he had tested it by its effect on the uterus in a case of midwifery.—Dr. CHURTON had given hyoscyamine largely, but had seen alarming symptoms when the respiratory centre had been weakened, as in cases of pneumonia.—In reply to queries, Dr. ALLAN said he had found ergotine of most use when the cough was violent and persistent, but it was of limited value in very acute cases either of bronchitis or phthisis.

Adenoid Vegetations in the Naso-pharynx.—Dr. BRONNER read a paper on the treatment of this condition. He related the history of the discovery of these growths, and showed the instruments used in their removal. He preferred operating without any anæsthetic but cocaine, and had found Dalby's "steel nail" very convenient. Several tubes filled with the removed growths were shown, and cases described.

Dr. J. GIBSON showed the original form of Dr. Bergeon's apparatus for injecting gases into the rectum. He had been using carbon disulphide in several cases of phthisis, and he showed a patient who had derived considerable benefit from the treatment.

Aneurysm of Thoracic Aorta, with Asthmatic Symptoms.—Dr. CHURTON showed this specimen from a man aged fifty. Although no physical signs existed, the presence of an aneurysm had been inferred from the fact that the attack of dyspnœa always came on if the patient moved about much, even in bed. The aneurysm, which was small, sprang from the third part of the arch, and was in contact with the bifurcation of the trachea.

Reviews and Notices of Books.

Prelectiones Anatomiæ Universalis. By WILLIAM HARVEY. Edited, with an Autotype reproduction of the Original, by a Committee of the Royal College of Physicians of London. London: J. and A. Churchill. 1886.

THE restorer of scientific anatomy was Andreas Vesalius; the inaugurator of a rational system of physiology, William Harvey. The discovery of the circulation of the blood is the cardinal fact which separates modern from ancient medicine, and in this discovery both Vesalius and Harvey took important though unequal shares. To the former undoubtedly belongs the credit of initiating that series of observations, experiments, and reflections from which the theory of the circulation was educed; to the latter belongs the glory of combining them and completing them by a scientific induction. Until the publication of Vesalius' memorable work, "De Humani Corporis Fabrica," in 1543, the authority of Galen in anatomy and medicine had reigned supreme for more than thirteen hundred years. It was acknowledged by Oribasius in the fourth century, Aëtius in the sixth, and Paulus Ægineta in the seventh; it dominated the Arabian physicians, both in the East and the West, for more than half a thousand years, and it prevailed in all the schools of Southern Europe from the twelfth century onwards. Avicenna, the greatest of the Arabian physicians in the East, and their most prolific writer, took the greater portion of his anatomical descriptions from Galen; and Albucasis of Cordova, the boldest surgeon of the eleventh century, and the best, laid special stress upon the necessity of surgeons being acquainted with anatomy as it had been taught by Galen, "uti illam tradidit Galenus." Even Mundinus, who at the beginning of the fourteenth century publicly dissected and demonstrated the human cadaver at Bologna, followed Galen only too closely; and the account of anatomy given two hundred years later by John de Vigo is mostly taken from Galen, the "prince of physicians," as De Vigo calls him.

It was Vesalius who first deliberately challenged the authority and supremacy of Galen, and it is noteworthy that among the errors which Vesalius detected in Galen was one which proved the starting-point of the discovery of the circulation. Vesalius denied the existence of the perforations through the cardiac septum. To fully appreciate the importance of this observation, it is necessary to call to mind the views which had hitherto prevailed respecting the functions of the vascular system.

The only complete theory of these functions which has come down to us from ancient times is that of Galen. According to the earlier Greek anatomists the vascular system consisted of two kinds of vessels—namely, *veins* (φλέβες) or bloodvessels proper, and *arteries* (ἀρτηρίαι), the conveyers of "air" or "spirit" (πνεῦμα). The veins were thought to arise from the liver and to be connected with the right side of the heart, and the arteries to be connected with the left side of the heart. The anatomists of the School of Alexandria taught that the veins received from the liver the blood, enriched by the products of digestion, and dis-

Digitized by Google

tributed it to all parts of the body by means of the superior and inferior cavæ, and to the lungs by means of the pulmonary artery. The arteries, on the other hand, arising, as the aorta, from the left ventricle, were also directly connected with the bronchi by means of the ramifications of the pulmonary vein within the lungs. By these channels the external air drawn into the lungs by inspiration had access to the left ventricle, being converted into *pneuma* in its transit through the lungs. From the ventricle the *pneuma* passed through the aorta into all the arteries of the body. Erasistratus (fl. B.C. 300), however, held that though in health the arteries were filled with *pneuma* only, they did contain blood in morbid states or when divided. But Galen showed by reasoning and experiment that arteries always contain some blood, which is thinner, brighter, warmer, and more *spirituous* than venous blood. Adopting the tenets of the Alexandrian School, that communications existed between arteries and veins in the substance of the tissues, he argued that an interchange took place between the contents of the two sets of vessels, some of the *pneuma* of the arteries passing into the veins and some of the blood of the veins passing into the arteries. He maintained, however, that these communications were not free enough or numerous enough to account for the great gushes of blood which occurred whenever an artery was wounded. He assumed, therefore, that a direct communication existed between the right and left ventricles by means of fine perforations in the cardiac septum. He admitted that these perforations were imperceptible—at all events, in the left ventricle. Notwithstanding this, no one questioned the existence of these hypothetical perforations, or the passage of blood through them, for nearly fourteen centuries. Mundinus believed in them, and so did Berengario da Carpi. But Vesalius maintained that, although depressions were to be seen on both sides of the cardiac septum, none of them, so far as the senses could determine, passed through; nor could any channels whatever be found by which the septum could be made pervious.

A few years after Vesalius had published his description of the *structure* of the heart, his ingenious but erratic contemporary, Michel Servetus, hazarded a happy surmise concerning its *mechanism*. In a theological work—"Christianismi Restitutio," published in 1553—Servetus alleged that the communication between the blood in the right and left sides of the heart did not, as generally believed, take place through the septum, but by a circulation through the lungs. This was the first distinct expression of the so-called pulmonary circulation.

The discovery of the valves of veins was the next most important contribution to the observations and arguments that prepared the way for Harvey's crowning discovery. Though valves had been occasionally seen in veins by earlier observers, they were first recognised as proper constituents of the veins by Harvey's teacher, Fabricius ab Aquapendente, in the year 1574, and were systematically described and figured by him in "De Venarum Ostiolis," published in the year 1603. It is true that Fabricius misinterpreted the purpose and significance of the valves, but his descriptions greatly influenced Harvey, who was then studying at Padua. Some years later the Hon. Robert Boyle asked Harvey what were the things that had induced him to think of a circulation of the blood. Harvey answered that it was a consideration of the position and distribution of the valves of the veins, which were so placed as to give free passage to the blood towards the heart, but opposed the passage in a contrary way. What use Harvey made of these and other contributory facts, and what were the merits and characteristics of his method, and what the final form of his exposition of the doctrine of the circulation, are sufficiently familiar to every educated man, or ought to be. The point of special interest just now is, that by a happy accident we have now an opportunity of seeing the doctrine in its earlier and more tentative shape.

In August, 1615, Harvey was appointed Lumleian lecturer at the College of Physicians. The office was then held for life. He began his first course in the month of April of the following year, and there have always been grounds for supposing that he first announced his views of the circulation in that course, though he did not publish his opinions to the world at large till twelve years later. A small manuscript volume, bearing the date 1616, and containing rough notes and memoranda for his lectures, was known to have existed, and to have been in the British Museum in 1766, when Dr. Lawrence wrote the Life of Harvey, prefixed to the College of Physicians' edition of Harvey's works. This manuscript, with another volume, also in Harvey's handwriting, formed part of the collection of Sir Hans Sloane, which became the property of the nation in 1753. Some time after it had been examined by Dr. Lawrence the volume was missing for many years. In the year 1877 it was found among the printed books in the Museum, and was restored to its proper place among the manuscripts. In the same year it was described in the Harveian Oration by Dr. (now Sir Edward) Sieveking, who read several extracts from it, and exhibited an autotype of one of its most important pages. Dr. R. Willis, in his Life of Harvey, published in the following year, referred to it and to Sir Edward Sieveking's labours, and asked, "Would it not be worthy of the Royal College of Physicians of London to have the entire volume deciphered and published?" This suggestion has at length been carried out.

Sir Edward Sieveking continued his investigations, and at his suggestion the subject was brought before the Royal College of Physicians on March 30th, 1885. The result is the handsome and interesting volume whose title stands at the head of this notice. The manuscript is, as Dr. Willis truly said, "a jumble of Latin and English with ever-recurring abbreviations," and written "in a hand so cramped and scratchy as here and there to try the best skill of the decipherer." Mr. Edward Scott of the Manuscript Department of the British Museum has, however, succeeded in making a transcript of the whole, "a work of great labour owing to the extreme obscurity of many pages of Harvey's writing."

The volume abounds with interest, historical, bibliographical, and personal. It gives us an insight into Harvey's character; it lets us see his method of work; it tells us the books he read, and shows us the uses he made them serve. There is, however, one page, the interest of which is pre-eminent. It has already been published by Sir Edward Sieveking in his Harveian Oration, but as the earliest known expression of Harvey's views is worth repeating. Harvey has himself marked it with the initials "W. H.," as indicating its originality and its importance:—

"W. H. Constat per fabricam cordis sanguinem per pulmones in Aortam perpetuo transferri, as by two clacks of a water bellows to rayse water. Constat per ligaturam transitum sanguinis ab arteriis ad venas. Unde Δ perpetuum sanguinis motum in circulo fieri pulsu cordis? An? hoc gratia Nutritionis, an magis Conservationis sanguinis et Membrorum per infusionem calidam vicissimque sanguis calefaciens membra frigifactum a corde calefit." (Page 80.)

Sir E. Sieveking renders it:—

"W. H. By the structure of the heart it appears that the blood is continually transferred through the lungs to the aorta—as by the two clacks of the water ram for raising water. It is shown by ligature that there is a perpetual motion of the blood from the arteries to veins. Whence Δ it is demonstrated that there is a perpetual motion of the blood in a circle, effected by the beat of the heart. Query: Is this for the sake of nutrition, or rather for the preservation of the blood and the members by the infusion of heat; the blood cooled by warming the members being warmed in turn by the heart?"

Here is the promise; the "Exercitatio anatomica de motu

ordis et sanguinis in animalibus" of the year 1628 is its ulfilment. Well may the editors declare, "The manuscript s to be regarded with veneration as one of the most precious f the archives of English science." It is but justice to add hat the form and style in which it is presented are creditable o everyone concerned in its production—to the College, he editors, the printers, and the publishers.

Might we suggest that, as the authorities of the Royal ollege of Physicians and of the Royal College of Surgeons ave purchased or guaranteed the cost of two hundred copies, ; would be a useful and graceful act to present a copy to he library of every medical school in England.

Neurectasy: the Bradshawe Lecture of 1883. By JOHN MARSHALL, F.R.S. London: Smith, Elder, and Co. 1887.

IT is with much pleasure that we announce the new dition of Mr. Marshall's Bradshawe Lecture, to which s appended by the author, and dated March, 1887, an ppendix, and twelve illustrations by Mr. Victor Horsley. To the last-named gentleman medical and physiological cience is indebted for the discovery of the nervi ner-vorum. Figures 8 and 9 represent longitudinal sections of human nerve stained with osmic acid, drawn by Mr. Horsley. The first figure shows a branching nervus vasis, mproperly described by Sappey and Krause as a nervus nervi accompanying a small bloodvessel. The second figure shows two true nervi nervorum arising from a branch of a primitive bundle, and running onward in the epineu-rium, doubtless to end in a tactile corpuscle or sensory nerve ending. Mr. Marshall says that Mr. Horsley "has proved beyond doubt the existence of sensory nervi nervorum, so that the conjecture I offered in my lecture on the existence of such nerves, and their relation to certain neuralgic pains, may now be regarded as having been completely verified." We may give Mr. Marshall's conclusions as to the practice of neurectasy or nerve stretching in his own words: "As regards its severity and its therapeutical results, nerve stretching may, speaking generally, be said to occupy an intermediate position between neurotomy and neurectomy, being more complicated in its effects on a nerve and more efficacious as a means of treatment than the former, but less decided and less radical than the latter. This general statement justifies the opinion that, as a rule, nerve stretching should be tried in a given case, if possible, before neurectomy; it nevertheless demands some further qualifications..... It is not only useless, but it is dangerous, and should be prohibited in all cases of serious central disease, such as confirmed ataxy, myelitis, fully established tetanus, pure epilepsy, and paralysis agitans. In reflex forms of epilepsy, in an ascending neuritis bringing about epileptiform seizures, in the early stages of a distinctly traumatic tetanus, provided that in any of these cases the peripheral source of irritation can be clearly localised and the affected nerve or nerves be accurately defined, nerve stretching may be serviceable, if employed soon enough." In peripheral disturbances of sensibility and motility the operation is certainly beneficial, but it appears to be less successful in spasmodic than in sensory or purely neuralgic peripheral disorders.

Analytical Records.

COCA WINE. (FOR FATIGUE OF MIND OR BODY.)
(ARMBRECHT, NELSON, & Co., DUKE-STREET, GROSVENOR-SQUARE, LONDON.)

THREE samples of this wine have been examined by us. One was sparkling, and had the flavour of a fairly good dry champagne; another was a Burgundy, and the third a Madeira. By analysis we easily isolated the cocaine, showing that the wine is really prepared with active leaves of the well-known *Erythraxylon coca*. Various statements of its value have been made, one of its strongest supporters being no less an authority than Sir R. Christison, who asserted from his own experience that its effect in removing physical exhaustion is remarkable.

ANTISEPTIC WALL PAPER.
(SINCLAIR & BROWN, VIRGINIA-STREET, GLASGOW.)

This paper is described as containing an antiseptic compound which is calculated to destroy the activity of infective matters upon the walls of dwellings. We separated the antiseptic, which has but little odour, and can therefore confirm the main statement of the inventors. There is merit in the idea, and we hope that experience will demonstrate the utility of the invention.

DR MIHL'S PERFECT HEALTH BISCUITS.
(THE INTERNATIONAL PATENTS ASSOCIATION, NICHOLAS-LANE, LONDON.)

These biscuits are well made from genuine wheat flour. The sample examined by us contained 6·33 per cent. ash, of which the greater part consisted of phosphates. We failed to find fluorine. They are very good biscuits, but we cannot see that they present any feature of novelty.

CARNRICK'S LIQUID PEPTONOIDS: CONCENTRATED BEEF AND MILK, WITH GLUTEN, PERFECTLY DIGESTED.
(THE MALTINE MANUFACTURING COMPANY, LIMITED.)

This is a clear, faintly acid liquid, which mixes easily with water. It yields a white precipitate of phosphate with ammonia, but is unchanged by acetic acid even on boiling. On distillation a liquid smelling like oil of cloves and containing some alcohol is obtained. When evaporated a great deal of syrupy residue is left which contains much nitrogen, and on ignition exhales an odour like burnt bread and leaves a white ash in which a large quantity of phosphate is found. We consider the preparation to be a very valuable condensed food.

CARNRICK'S PEPTONOIDS; WINE AND IRON. COMBINATION WITH PYROPHOSPHATE OF IRON IN BEST SHERRY WINE.
(THE MALTINE MANUFACTURING COMPANY, LIMITED.)

The basis of this preparation resembles the last, and is probably identical with it. It is a clear and agreeable wine, which mixes freely with water, is not precipitated by acetic acid even on boiling, but yields a distinct precipitate with ammonia. The iron is readily found by ordinary methods. It is a very powerful and agreeable tonic and stimulant.

EAUX MINÉRALES NATURELLES DE VALS: ST. JEAN.
(W. BEST & SONS, HENRIETTA-STREET.)

This is a very interesting natural water. The sample we have examined contained 219·5 grains per gallon of solid matter. It is an aerated water, and its chief constituents are the bicarbonates of sodium, potassium, lithium, calcium, and magnesium. Sulphates and chlorides are present in small quantities, and iodine in very notable quantity. All these we have found by analysis. The flavour of the water is agreeable, but there seems to be somewhat more organic matter than is desirable. Close attention should be bestowed upon the surroundings of the spring for some dark flakes were found in suspension in one sample, which were at least unattractive.

OZONE PAPER. (FOR THE IMMEDIATE RELIEF OF ASTHMA, CHRONIC BRONCHITIS, AND BRONCHITIS-ASTHMA.)
(R. HUGGINS, 199, STRAND, LONDON.)

These papers, in which chlorate of potassium is readily detected, deflagrate readily when ignited, and are very convenient. All our readers know how valuable the remedy is in certain cases. We think, however, the title requires some qualification.

SUNLIGHT SOAP.
(LEVER BROTHERS.)

This is a good neutral soap, which gives a perfectly clear solution with water, and yields an excellent lather in cold water. We found no caustic alkali in it, but some glycerine, which is an improvement. It is soft and pleasant in use. The pamphlet which accompanies the soap contains some excellent directions for washing in lukewarm water. If laundresses would only follow them, they would save themselves labour, and the goods would last much longer.

THE LANCET.

LONDON: SATURDAY, JUNE 11, 1887.

RATHER more than two years ago we urged upon the Government the appointment of a Royal Commission to inquire into the subject of over-pressure in elementary schools. After a year's delay the Commission issued directed the Commissioners to inquire not only into over-pressure, but generally "into the working of the Elementary Education Acts (England and Wales)," and the first instalment of the report appeared last year. The evidence then published, however, was chiefly collected from official witnesses, and was directed rather to inquiries into the working of the law and the efficiency of the existing machinery than to the discovery of over-pressure, and of the causes to which it might be due. On these points the public has had to wait for the second report, which was issued only at the end of last week. The witnesses whose evidence is here collected are for the most part teachers and managers in actual and daily contact with the children of the schools, from whom, therefore, the most important facts respecting over-pressure might be elicited, and to whose testimony accordingly the public will look with the liveliest interest for information on this profoundly important subject.
